AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M.,
EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.

Published both in English and German.

{ \$1.00 PER ANNUM, IN ADVANCE
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 32.

VOLUME XXII—No. 1.

NEW-YORK, JANUARY, 1863.

NEW SERIES—No. 192.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York.
Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

We take pleasure in beginning our work for the year by presenting to each of our readers, the "Compliments of the Season." That the year now opening may be to each and all of them a "HAPPY NEW-YEAR," is our earnest wish. May it be rendered happy from the beginning to the close—to the farmer by abundant and profitable returns for his labors in the field; to the house-keeper by a diminution of anxious care, by freedom from severe illness in her family, by success in all her efforts to render home more attractive, more home like, than ever before; to the children and youth, by exemption from sickness, by vigorous growth of both body and mind, and by improvement in their habits and morals; to our common country by the return of peace, founded upon such principles as shall render that peace a perpetual one.—That our readers may secure the happy year we wish them, we shall on our part spare no labor or thought. We look at half a million sheets of pure white paper already in store, with as many more to be added, and the thought comes up that all of these are to be covered with the symbolic marks that convey ideas, and then be scattered broadcast over the land. May we be able to send forth such words, such thoughts, such hints and suggestions, as shall be best calculated to promote the pleasure and profit of all who peruse these pages.—We note down in these first columns some hints which, if not specially instructive, will at least serve as reminders of work to be done. The labors of the month will always go on more regularly, and be better done, if a well digested plan be laid down. Our first hint then is: Sit down with paper, and pen or pencil, and lay out the work for Janu-

ary: What must be done, what ought to be done, how much can be done, what must be done the first week, the second, and so on. Into this calculation must enter the probable interruptions and delays. This and the following month are essentially the farmers' resting season, though the care of stock, the providing of a year's fuel where wood is burned, the unfinished work in the grain department, and perhaps among out-standing corn, especially at the West, with other items detailed below, will keep many farmers pretty fully occupied. It is well to remember, however, that a bow that is always bent loses its elasticity; so, every farmer at least should at this season, lay on some extra muscle, and recruit his vigor for the exhaustive labors of the Spring, Summer and Autumn.

Work for the Farm, Household, etc.

Account Keeping.—Some system of keeping accounts is essential to the best success of every farmer. A sheet or two of paper with a debtor and creditor side, is better than nothing. On one side put down every item owed, and to whom; and on the other, note every item due. Sum up the condition of your worldly possessions in two columns. Every day's transactions, whether cash or credit, should be written down with the date. This should include every purchase for ready money, or on time, of a neighbor, or at the store, etc. It would pay well to have a debt and credit account with each kind of farm labor, with each field, each kind of animals, of family expenses, etc. Such accounts lead to thinking, to investigation, to carefulness. The written record to refer to, would prevent not a few of such scenes as are portrayed on page 9. Skill in book-keeping is not required; "quail tracks on paper," barely plain enough to be understood, are far better than no record.

Buildings.—Replacing a shingle on the roof of the house or barn may save much damage from leakage. Hundreds of roofs fall in every year from accumulations of snow. If the rafters and covering are known to be abundantly strong, no further care is needed; otherwise remove any extraordinary deposits of snow. A wooden hoe on the end of a long pole will answer. An extra strip of wood, or of listing, on the window or door casings may shut out much cold. We have seen a man using half his spare time in cutting, hauling, and carrying in wood to keep up a rousing fire, when there was an inch crack under the outer door that let in cold air enough to use half of the heat produced. An hour in stopping that crack would have saved forty hours spent at the wood pile, and added greatly to the comfort of the house. He "saved at the tap and wasted at the bung-hole." Better spend one day in stopping up the cracks, than ten in keeping up the fire. Some time since, we showed how cotton was worth \$10 a pound; a pound of it in the cracks and crevices shut out more cold than \$10 worth of fuel could

drive out.... We repeat last month's hint, that the less outside protection a man or animal has, the more food must he consume to keep up the internal fire. Make not only the house, but the stalls, the sheds, and the styes, warm; make the animals comfortable, and far less food will be needed. A double floor or a warm cellar underneath will also save fuel and food, and promote health. See "Children on the Floor," page 21.

Cattle.—In brief, make them comfortable; they will look better, feel better, eat less, be more healthy, and be worth far more in Spring. Every animal should have some shelter from wind, rain, and snow. If not a stall, then a good shed. If on a new farm on the prairie, where timber is yet too scarce and costly for your means, a rail pen covered around and above with straw or stalks, will well pay for its cost, in the better condition and growth of the animals. If water is scarce, better melt snow over the fire than to compel them to eat snow. Extra fuel (food) must be supplied to keep up the fire in their bodies, if snow is melted there. The extra digestion required for this, detracts from health, vigor, and growth. Remember the salt rations at least twice a week. That weak animal will continue a "runt," if kept from a full supply of food and from shelter, by another overbearing animal. Give it some protecting division line.

Cellars.—Foul air breeds decay. All rubbish, or rotting vegetables should be removed. Families living in a new or swampy country suffer from malaria; decaying vegetables in the cellar send up similar gases through the house or barn cellar. If damp, a few boards or straw on the bottom, to walk on, may save wife a cold, perhaps a fit of sickness, if she goes there often from a warm room, with thin shoes on. Ventilate as often as the weather will permit, but stop out the thief Jack Frost, with an extra bank of earth or tan bark, if the walls be not amply thick and impervious. An hour's frost may destroy the products of weeks of toil. A coat of whitewash, put on the walls and ceiling even now, will promote neatness and sweetness, and save the necessity of an extra light, if the windows be deficient or in part covered. The best windows are those with double glass, half an inch to an inch apart, and the sash on hinges. Room may be saved by having the sash hung at the top to swing up to a hook.

Colts.—See hints on page 11. Care in breeding, and in feeding also, has produced our improved horses. Stunted colts make stunted horses. By means of good nourishing food, not over-graining, you may develop large muscles, strong bones, capacious healthy lungs, and turn out a far more valuable horse for any kind of work,

Club Meetings.—Farmers need the benefit of these more than any other class. Mechanics, merchants, and business men generally, come more in contact; their ideas are rubbed up bright

by practice; they learn from each other's methods; they talk more about their work and the best way of doing it, than farmers who are separated from constant intercourse by their broad acres. The meetings for social chat about farm matters held at the school house, or from house to house, are of great utility. No one ever attended such a meeting without carrying home some new hint, or having a new train of thought started. Too much formality, too long a constitution and bye-laws, are to be avoided. The more familiar, conversational they are, the better. Every neighborhood in which they are held will be benefited, and their effects will be seen not only in greater crops, better roads, tidier farms, and better stock, but in healthier, and happier inhabitants. Especially should the young men be induced to take part in these meetings: they should be taught that agriculture is ever progressive, and that he who does not keep pace with it, must be, like Tim Bunker's neighbor, Jake Frink, always "runnin' astarn." (See Dec. *Agriculturist*, page 364.)

Hogs.—Those to be slaughtered will lay on fat all the faster for being kept warm. Those having large numbers fattening on the western prairies may hasten their plans and save corn, by providing good nests, if not in warm pens, then among the stalks, or in straw heaps. It will pay to dig pits for them in the ground, covering with straw or sheltering to shut out cold and storms. Feed the lighter grains and soft corn first, finishing off always with good sound corn. Experience proves that it pays well to grind and steam hog food.—Store hogs, those kept over, will at the East, almost pay for their board in making manure, if rightly managed. See rules for making "Prime Pork," on another page. Supply them plentifully with coarse litter, forest leaves, straw, etc., and they will manufacture a valuable fertilizer without the help of machinery, without the help of an overseer, even without instructions. Give fattening hogs plenty of cooked food, and provide good shelter for all.

Horses.—Avoid sprains and hoof diseases from frozen ground, or snow and mud slush, by prompt and careful shoeing; prevent coughs and colds by comfortable blanketing when standing in cold winds and promote general health by just enough of good food, and by comfortable, clean, light, and ventilated stables, and frequent cleaning and rubbing.

Humbugs.—Look out for them. They always come upon one unawares in a new and attractive garb—golden-tinged. When anything is offered astonishingly cheap, look out for a cat in the meal, especially if it is an article with which you are not familiar. See notes elsewhere.

Ice.—Get in a full supply as soon as sufficiently thick and solid. In the better preservation of food in hot weather, and in case of sickness alone, it may be worth its full cost, to say nothing of the luxury of having at hand a supply of "pickled coolness" in midsummer weather. Ice is not difficult to keep. A rough shed about 12 feet square and 10 or 12 feet high, well roofed and out of the sun, with enough of clean saw-dust to fill in five or six inches thick between the ice and the boards, and also to cover it well, will preserve enough ice for a season's supply for an ordinary family. If the shed is not built, erect the frame and cover it; then pack in the ice in freezing weather, and sprinkle on water enough to fill up and make the pile a solid block. Then commence at the bottom to fasten on the outside boards and fill in the sawdust as the boards rise. A double frame that would admit of sliding the boards in between the posts, would enable the filling to be done in this way, year after year.

Implements.—There may be a scarcity of farm laborers during the coming season, and those who secure the best labor-saving implements will be fortunate. Though these can not all be practically tested in Winter, it is well to be on the lookout for information relative to them. Visit first class farmers, bring up the subject in farmers' club meetings, and read agricultural publications. A day devoted to finding an implement that will save a week's labor, besides paying good interest on its cost, is time well spent. By all means see that

those already on hand are in good repair, and well preserved from rust, rot and accident. As hitherto frequently suggested in the *Agriculturist*, a coating of three parts of lard and one of rosin melted together and rubbed on them, will prevent iron and steel from rusting.

Manure.—Our Western readers, on the virgin soils, where organic matter yet abounds, usually skip the manure articles. Eastern farmers, on the old lands, are annually learning more of the value of good manure. A few loads of good manure per acre will often double a crop without increasing the other expenses of preparing the ground, seed, and cultivation. Every kind of animal or vegetable matter, from the dead carcass, to the black earth in the woods or swamp, will by decay furnish nutriment to any growing crop. The compost heap is the gold mine of the farm. Into this heap, let every handful of animal droppings go, and with these all the vegetable matter possible, the leaves from the forests and elsewhere, black earth from the woods and swamps, sods, weeds, etc. The heterogeneous mass, frequently forked over and well rotted, will tell on next Summer's crops. See article on covering manure, page 14.

Marketing.—An important feature in successful farming is judicious marketing. Many farmers must sell as soon as possible, but it is desirable to have good facilities for reaching the market, and also to be so forehanded as not to be obliged to sell when fair prices can not be obtained. The farmer can then watch the market reports and study the probable home and foreign supply and demand, and determine with considerable accuracy when it is best to sell. The farmer who gets \$1 per bushel for his wheat realizes double the profit that he does who only gets 50 cents, provided the cost of producing is with both 60 cents per bushel. It pays to study marketing well, and also to prepare and put up in the best manner all perishable produce, such as butter, poultry, fruit, pork, vegetables, etc.

Plow heavy soils deeply, in mild spells of weather, when dry enough, and thus secure the benefits of freezing and snow, which are often of great value.

Poultry will pay for good housing, feed, and care now. Eggs retail here in the city, at this season, for 25 to 35 cents per dozen, and the buying price is correspondingly high. Give the fowls gravel and sand to scratch in, with grain and bits of meat. A little lime or powdered oyster shells, vegetables, ashes, and plenty of pure water should also be supplied. The opinion that fowls need no water, leads to the prevalent custom of leaving them to get their liquids from the filthy yard, or by eating snow and ice. Give the fowls, especially the laying hens, a constant supply of clean water.

Roots stored in cellars or in pits for feeding out, may require additional protection from frost. They need some ventilation, otherwise the dampness from evaporation of their juices which is continually going on, will make the surrounding air a good conductor of heat, and they may be frozen. If any are decaying, remove them at once. In feeding, give them as a relish with dry food, rather than as a staple article of diet.

Seeds. Keep in a dry and cool place, away from rats and mice; these are particularly fond of pumpkin and squash seeds. A little care now will save much annoyance at planting time. Now is the time, if not already done, to get ready all seed needed in Spring. It is always high at seeding time.

Sheep need a few roots, turnips or potatoes, daily, with the other dry food. Do not suffer them to lose flesh now. Keep sheep separate from other animals, liable to worry or injure them. It is not too late to put bucks with ewes for lambs to be dropped during the first of June.

Steers. Commence handling while young, as they are then more within one's power, and readily become accustomed to being controlled. Do not load them heavily, or treat them harshly. Give them full opportunity to learn what you want of them, before expecting obedience.

Wood. Store a plentiful supply in a dry place. The finer it is cut, the more thoroughly it will dry, the quicker it will boil the dinner, and the better answer every good purpose. See remarks on green and dry wood in November Calendar.

Orchard and Nursery.

Not much active work can be done in this department the present month, and but few hints are needed in this month's Calendar. In laying out the plans for the year, it may be well to inquire, whether more trees may not be planted with profit. Fruit trees do not require much ground the first five years, and when they do, their products repay the loss of surface. How much does it cost to raise and to annually tend a tree that in a few years will return large crops of apples or other fruits? It will be economy to now look up and engage the trees desired in Spring, so that they may be provided for, and ready to come at the best dates. Most of the leading nurserymen have catalogues of names and prices, which they furnish free to applicants inclosing a stamp for postage. See valuable list of pears on page 17.

"A penny saved is earned." A single day's labor seasonably and judiciously devoted to precautionary measures in the Orchard and Nursery, may save both money and vexation of spirit. Domestic animals, rabbits, mice, strong winds, etc., are ever liable to produce injury, and should be fully guarded against. Good fences, kept in good repair, are the best protection against domestic animals, but these are of little avail, if the gates are left open, as is often the practice in Winter. Various methods are employed to protect the trunks of trees from the attacks of rabbits. They may be bound with paper near the base, which is to be besmeared with tar. One of the simplest, easily applied, and most effective protections of the base of the trunks of small trees, is to set around them two horse-shoe drain tiles, fastening them together with a wire wound around. Of course, neither mice nor rabbits can injure trees so protected. Dried grasses or weeds, or banks of snow furnish good breeding places for mice. The removal of the rubbish, and the hard tramping of deep snow around the trunk should be attended to when mice are troublesome.

Occasional attention should be given to staking and tying up trees swayed by strong winds.

Cions for grafting, and cuttings for propagation may be made in January or February before the sap starts. Put them in boxes of barely moist sand or earth, in a cool part of the cellar. They will thus keep well for months. Cut these from thrifty, well matured wood of last season's growth.

Drainage is quite as important for fruit trees, as for farm crops. Trees standing in a wet, damp soil are injured by freezing, and the soil is cold and damp all the year. No water should stand in hollows around the trees. A deep drain run near a fruit tree often acts like magic upon its growth and fruit bearing. In open weather this month, new drains may be opened to advantage.

Large fruit trees and deciduous (leaf shedding) shade trees may be moved with convenience and safety during the coldest weather, by cutting out and taking up around the roots a considerable mass of frozen earth. We assisted in successfully moving a shade tree two feet in diameter. A deep channel was cut around the trunk at the distance of 4 to 5 feet. The frozen mass was dug underneath, and boards worked under, with one end on the surface. Bundles of trees were placed around the bark to protect it, which were held in place with a heavy chain, to this were attached three yokes of oxen. A dozen ropes from the branches on every side, to steady the tree and keep it upright, were held by several neighbors, who volunteered to assist. The tree was slid along on boards and planks laid down, and it was thus moved some 50 feet into a new hole, and loose soil packed in around the frozen earth. A large heap of stones put on, kept it from blowing over during the first year. The tree grew and flourished, as if nothing

had happened to it. Smaller trees may be readily moved without so much labor.

Stakes and labels should be prepared in Winter. Some recommend to make them more durable by soaking them in a solution of 1 lb. of blue vitriol in 3 gallons of water. Straight grained pine, sawed into suitable lengths, and split and whittled smooth, are the simplest and most easily made. A notch is required on both sides of one end, to tie by. A little thick white paint, rubbed on with a cloth before marking, preserves them, makes the letters more visible, and the paint fastens the pencil marks.

Those intending to plant trees next Spring, are recommended to excavate large holes now (if not already done) where trees are to be set. The frost and snow greatly ameliorate the subsoil. Besides this benefit, important time in the busy season is gained. It pays well, at least on heavy soils, to expose the subsoil of the whole area of the new orchard, in Winter, to the action of snow and frosts.

Kitchen and Fruit Garden.

In northern localities the ground is either frozen or covered with snow so that but little can be done during the present month. Still, the garden should occasionally be visited to see that all is going on well. If water stands on any places occupied by crops it should be removed by surface drains, if underdrains be not practicable at once. See that fences are tight and gates properly fastened, to all enclosures containing fruit trees and shrubs. A hungry stray animal will do irreparable injury in a few hours if allowed to enter the garden. Much can be done in planning to facilitate Spring work. Every garden of moderate dimensions should be mapped at leisure, and all projected alterations or improvements indicated. The place for all the main crops should be marked upon the map. It is quite important to have a regular rotation of crops, there being scarcely any vegetable, save onions, that succeeds well on the same ground year after year. In arranging the planting map, those plants liable to mix should be put as far apart as possible; this is especially important for squashes and melons and the different varieties of sweet corn. In open weather the ground may still be plowed if not too wet.

Bean poles, Stakes of all kinds, Pea Brush, etc. Now is the best time to get a good supply. If left until Spring work begins, it is very apt to be hurriedly done or neglected. If the lower ends of the poles be soaked in a solution of 1 lb. of blue vitriol in 12 quarts of water they will be more durable. White birch, where obtainable makes good pea brush.

Cold Frames.—Protect in severe weather by straw mats covered by boards or shutters. A covering of snow helps protect the plants. In mild weather ventilate and let the plants have light.

Cuttings of Currants, Gooseberries, etc. If these were not made in Autumn, secure a supply now, at times when they are not frozen. Bury them in moist but not wet sand or soil, in boxes in the cellar. They may be buried in the cellar bottom, if moderately dry ground.

Hot-Bed Frames and Sashes.—Old ones should be put in order and new ones made or purchased. Every garden should have a hot-bed; they are cheaply constructed and easily managed by any one of ordinary intelligence. Almost all kinds of vegetables are easily obtained some weeks earlier. The sash should be six feet long, and wide enough to contain 4 rows of 7x9 glass. The sides of the sash should be heavy enough to prevent springing; this may be obviated by an iron rod secured midway across the sash. Unless one is a very clever workman, it will be found cheapest to purchase the sash ready glazed. The glass should lap about $\frac{1}{4}$ of an inch and be well secured by points and putty at the sides. No putty is required where the panes overlap. The frames should be made of plank, firmly nailed together. They may be one foot high in front and two feet high at the rear, and of a length suitable for two or three sashes if so many are used.

Seeds.—Examine the supplies on hand, and see that they are safe from mice. Note the kinds which

it will be necessary to purchase and examine seedsmen's catalogues. Experienced persons can judge of the quality of seeds by inspection; where there is any doubt, it is safer to test them before purchasing a supply. Placed in earth or sand, not too wet, in a warm room, they will soon germinate if good.

Tools.—See that all are in good repair and carefully housed. One man with good tools will do as much work as two men with poor tools, yet the difference in the cost may be less than the expense of a very few days' work.

Flower Garden and Lawn.

If any improvements are to be made here, let the plan be well considered and placed upon paper so as to be worked from....When snow accumulates on evergreens, a slight jarring will throw it off and prevent their being broken down....Walks and carriage drives may be made during mild weather. Dry walks should be secured by placing a drainage of coarse stones below the gravel....Prepare an abundance of neat labels and stakes, in anticipation of the busy season....Flower pits should be allowed air freely when the temperature is not too low. Give water sparingly if the soil is very dry; keep them carefully closed and covered during very cold weather. Look out for mice....If trees are to be planted in the Spring, holes may be made now whenever the ground is open. The frost will greatly ameliorate the soil and fit it for the reception of roots. Large trees may be moved with a ball of frozen earth, as suggested under Orchard above.

Green and Hot-Houses.

Care and judgment will be required to maintain a proper temperature. Listing the cracks and putting on shutters in very cold weather, will save a large amount of wood or coal—the latter an important matter at its present price. In the Green-House, where but little or no growth is desired, the temperature should be kept between 40° and 50°. In the Hot-House the range should be from 65° to 70°, and moisture of atmosphere and other conditions of rapid growth maintained. Look after ample ventilation when the out-door temperature is not low, and arrange for plenty of light. The importance of light is not always apparent to novitiates.

Azaleas require water as they increase in growth.

Bulbs.—Those desired to bloom soon are to be transferred from the Green-House to the Hot-House, where the higher temperature will favor their rapid growth. Change water in glasses every two weeks.

Calceolarias.—Re-pot those needing it. Turn frequently, presenting all sides equally to the light to induce upright growth.

Camellias should now delight the lovers of the beautiful, with a fine bloom. Water and syringe foliage every three or four days, but avoid wetting the flowers, as this will hasten their decay.

Carnations, etc.—Set cuttings to provide plants for early Summer bloom in the open air. Stake those in bloom, and water frequently. Those becoming pot-bound need shifting to larger pots. Cuttings also of petunias, verbenas, pelargoniums, etc., for bedding out in Spring, may now be made. Those planted last month are ready to pot off.

Fuchsias.—Re-pot growing plants. The imperfect ones will answer well for cuttings.

Grapes.—Those well advanced require plenty of air and but little water at the roots. If mildew appear, syringe with water in which a little sulphur is sprinkled. Thin out, and prune if needed.

Insects.—Guard against them as much as possible, by cleanliness, washing or syringing foliage, hand picking, etc. If they appear, use tobacco fumes for thrips or green fly, soap and water for scale, and clear water with sponge or syringe, for red spider.

Manure.—Stimulate growing plants every two weeks or so with dilute liquid manure, until plants are about to bloom, then discontinue.

Oranges, Lemons, Oleanders, and Myrtles should

now be put in a situation to favor a moderate growth. Clean their trunks and branches from insects.

Peach, Nectarines, Figs, and other fruit trees in pots, should now have a warm growing position, and re-potting if needed. Give liquid manure occasionally, and look for fruit the latter part of June.

Soil.—Have a supply ready for use where it will not freeze. Directions for its preparation have been frequently given in previous numbers.

Seeds of many hardy annuals may now be sown for transplanting early to open air borders.

Water will be needed frequently this month, especially in those houses requiring considerable heat. A mere sprinkling of the surface is not sufficient. It is well to plunge the whole pot into the water tank if the foliage begins to wilt. Fire heat often dries the earth in the bottom of the pot when the surface is moist. Keep a tank, cistern, or barrel, always full of water in the house itself, that it may be of the same temperature.

Apiary in January.

This is a period of inactivity in the hives. For those out of doors little can be done except to secure proper ventilation, which is quite as necessary now as at other seasons, and to guard against the depredations of mice. Ice may chance to close every aperture and the bees be smothered. If mild weather occurs, and the frost leaves the hives, they may be lifted to allow the removal of dead bees and accumulated filth. Mice and other vermin may be kept out by closing the openings with wire cloth, leaving a hole large enough for the passage of a single bee. When snow covers the hives let it remain, if proper care has been taken to keep out the mice. While the sun should be allowed to fall upon the hives in very cold weather, they should be shaded during the warm spells. The bees may be tempted to fly during mild days, and may be allowed to do so unless the ground is covered with recently fallen snow. Bees that are housed require but little attention, and should not be disturbed any more than is necessary to make sure that they are secure from the attacks of vermin.

Seasonable Directions for Mess Pork.

The following standard rules, known as "Getty's Directions," are those given for putting up Prime Mess Pork, to meet the requirements of the English market. They are also adopted and made imperative, in the contracts given out for Army Supplies by the United States Government.

QUALITY AND WEIGHT OF PIGS.—The Pigs to weigh from one hundred to one hundred and sixty pounds each, and to be in good condition, strictly corn-fed or hard Pork. For the United States army the weight may be extended to one hundred and seventy pounds.

PARTS EXCLUDED.—The head is to be excluded, also the fore leg up to the breast or brisket, the hind leg including the hock or gambrel joint, and the rump, if the hams are not cut up with the sides.

WHAT CONSTITUTES A BARREL OF PRIME MESS.—A barrel of Prime Mess Pork consists of fifty pieces of four pounds each. If the hams are cut up and put in, there shall not be less than twenty-three side-pieces; if without hams, not less than thirty side-pieces.

HOW TO CUT AND CURE.—After the Pig has been split through the back, cut each side longitudinally into two strips; pack the strips into large casks or vats, and fill up with brine, having saltpetre added at the rate of one ounce to three gallons of brine; leave the strips in the brine for eight or ten days to extract the blood, and for the lean meat to take a pink color.

When ready to be packed into barrels, have each strip carefully cleaned, using a knife and brush if necessary; cut them into four-pound pieces as nearly as may be; Mess (select the pieces) as indicated, and pack neatly and compactly in layers, with sufficient salt to preserve it.

BARRELS.—The barrel should be twenty-eight inches long, and seventeen and a half inches over the end (when finished) made of seasoned white oak free from sap, full bound with hickory or white oak hoops, and one iron hoop (one inch wide) on each end next below the chime hoop.

THEORY OF MESSING.—Pigs averaging say one hundred and forty-five pounds, will work up in messing about as follows: When the side, including the ham, is cut up there will be twenty-three or twenty-four pieces of side-meat, eight pieces of ham and saddle, and eighteen or nineteen of shoulder and neck to the barrel; excluding the hams, the number of side-pieces will be increased to thirty-one or thirty-two. In no case should there be more than six pieces of the leg part of the shoulder put into a barrel.

Seeds for Free Distribution to all Subscribers for 1863 (Vol. 22.)

See General Remarks on Page 8, and the Descriptive Notes below.

Every subscriber to the *Agriculturist* for 1863, is invited to select **three or four parcels** of seeds from the list below.

These seeds are all valuable. Of the 63 kinds offered, many are comparatively new varieties, but we include some common, useful sorts for convenience of those without access to good seeds.

Most of them are annuals (reproducing seed the first season), and in all cases there will be enough to yield a supply of seed for future use. Our aim is, to furnish the *germs* of future abundance in each locality where these seeds go.

Many of these seeds were grown by ourselves, the past year; the others are obtained of the best growers. The distribution will begin in February. A description is given in the next columns.

Mode of Distribution.—The seeds may be called for at the office, after March 1., or be applied for by mail at any time now, to be forwarded as soon as ready. The postage is only **1 cent per ounce under 1500 miles; and 2 cents per ounce when over 1500 miles.**

Those sending for seeds to be forwarded by mail, will please carefully observe the following

DIRECTIONS.—(1) Select from the list below, any **three or four parcels** desired, and write **plainly** on a slip of paper the **numbers** (only) of the kinds of seeds wanted. (These numbers are used on our seed drawers, seed bags, etc.)

(2) Enclose the slip in a prepared envelope—directed in full to **your own address** (not John Smith's), and put on it postage stamps to the amount of **one cent for each ounce of seeds to be enclosed**, if to go **under 1500 miles, or two cents if to go over 1500 miles.** (Most places West of the Mississippi river are over 1500 miles.) **N.B.**—The total amount of stamps required can be reckoned from the table of seeds below. Any fraction over even ounces will need an extra 1-c. or two 1-cent stamps according to distance. Forward the above prepared envelope to this office, in a letter, and the seeds will be enclosed according to the numbers on the slip. To save postage, let there be **no marks on the envelopes** except the address and stamps. About 2 ounces will go in a common sized envelope.

John Smith,
Albia,
Monroe County,
Iowa.

Field, and Vegetable Garden Seeds.

No.	Weight of package.
191—Mammoth Millet.....	About one-half ounce.
141—Darling's Early Sweet Corn.....	About one ounce.
187—Stowell's Evergreen Sweet Corn.....	About one ounce.
187—Corn, Broad Leaf Tobacco, Less than one-eighth ounce.	About one ounce.
187—Genuine Havana Tobacco, Less than one-eighth ounce.	About one ounce.
8—Daniel O'Rourke Pea.....	About one ounce.
9—Champion of England Pea.....	About one ounce.
12—Green Kohl Rabi.....	About one-fourth ounce.
145—Flat Dutch (Winter) Cabbage.....	About one-fourth ounce.
218—Early Sugar Leaf Cabbage.....	About one-fourth ounce.
193—Red Dutch Cabbage.....	About one-fourth ounce.
64—Extra early Round Turnip Radish; one-fourth ounce.	About one-fourth ounce.
19—Round Spinach.....	About one-half ounce.
147—Neapolitan Cabbage Lettuce.....	About one-fourth ounce.
101—Improved Long Orange Carrot.....	About one-half ounce.
149—Extra early Bassano Beet.....	About one-half ounce.
95—Hubbard Squash, pure.....	About one-fourth ounce.
193—Fejee & Italian Red Tomato.....	About one-eighth ounce.
154—Ice Cream Water Melon.....	About one-eighth ounce.
217—Fine Nutmeg Melon.....	About one-eighth ounce.
191—Hollow Crown Parsnip.....	About one-fourth ounce.
152—Fine Large Cheese Pumpkin.....	About one-fourth ounce.
17—Red Strap-Leaf Turnip.....	About one-fourth ounce.
195—Early Short Horn Carrot.....	About one-fourth ounce.
196—Green Curled Kale.....	About one-fourth ounce.
198—Improved Purple Egg Plant.....	About one-eighth ounce.
197—Linnaeus Rhubarb.....	About one-half ounce.

Flower and Ornamental Seeds.

89—Cotton Plant (2 kinds, mixed).....	One-half ounce.
111—Castor Oil Bean.....	One-half ounce.
On an average any five of the following varieties will go under one 1-cent stamp, (or two stamps if over 1500 miles.)	
200—Fancy Gourds, (mixed varieties) (ha)*	203—Mixed G'n Poppy, (ha)
23—Mignonette, (ha)	204—Mixed F'n Poppy, (ha)
30—Tassel Flower, (ha)	205—Double French Marigold, (ha)
31—Chinese Pink, (ha)	206—Golden Straw Flower, (everlasting) (ha)
37—Beautiful Zinnias, (Mixed) (ha)	210—Convulvulus minor, (ha)
49—Candytuft, (ha)	212—Fine Sweet Peas, (ha)
51—Drummond's Phlox, (ha)	219—Martynia in var. (ha)
123—China pinks, (ha)	230—Perilla nankinensis, (ha)
124—Wildlavina, (ha)	221—Striped Mirabilis, (ha)
126—Long tubed Centranthus, (ha)	227—Cockscomb, (ta)
164—Sweet-scented Ageratum, (ha)	222—Convulvulus variegata, (ta)
169—Clarkia pulchella, (ha)	216—Acroclium roseum, (ha)
173—Mixed Larkspur, (ha)	123—Mixed Canterbury Bells, (hb)
177—Gracelil Quaking Grass, (ha)	170—Evening Primrose, (hb)
182—Sweet Alyssum, (ha)	42—Foxglove, (hp)
183—Fine Mixed German Asters, (ha)	209—Dw't Blue Larkspur, (hp)
	223—Mourning Bride, (hp)

* (ha), hardy annual; (hha), half hardy annual; (ta), tender annual; (hb), half hardy biennial; (tb), tender biennial; (hp), hardy perennial; (hbp), half hardy perennial; (tp), tender perennial.

Descriptive Notes.

The notes below will afford some information upon the character and cultivation of the several plants, wherever the seeds may be obtained, and they should be preserved for reference in the Spring planting season. More full directions for the culture of these and other plants will, of course, be given from time to time, in separate articles. The Calendar of Operations, from month to month, will also suggest the time of sowing or planting. Most of the field seeds are necessarily in too small quantities for a crop, but with a little care in culture each parcel will produce a fair supply for a good-sized crop the next year. To avoid confusion, and save time by system, we shall not

begin the mailing until all seeds and parcels are ready, say the latter part of February, except those sent to very distant points.

For brevity, the *Numbers* are always used in putting up and sending out seeds, and subscribers are particularly desired to note this in their application. To avoid confusion, we use a new number for each addition, dropping the numbers of any seeds previously offered, but not retained in this list.

Field and Garden Seeds.

No. 8.—**DANIEL O'ROURKE PEA.**—An early sort of fair quality, grows 2 feet high, and may be eaten in 40 or 45 days from planting. Sow from first to last of April, according to climate, or any time in May to multiply seed.

No. 9.—**CHAMPION OF ENGLAND PEA.**—A later, tall-growing variety. One of the very best; is our chief dependence for a table pea through the season. Sow as No. 8, or at intervals until July, if seed is plenty.

No. 12.—**GREEN KOHL RABI, OR CABBAGE TURNIP.**—The eatable part resembles a turnip, and grows above ground. Plant early in May, the same as turnips, and for table use boil the bulbs only while still tender. This is largely used for cattle and sheep in England.

No. 17.—**RED STRAP LEAF TURNIP.**—A very quick-growing variety of the flat Dutch sort, with a reddish or purple top. They are good for the table, while growing, and for stock during Autumn and early Winter. Sow in drills from the first of April to August.

No. 19.—**ROUND SPINACH.**—The best for Spring and Summer greens. Sow in good soil in drills 15 inches apart and thin to 8 inches in the rows.

No. 64.—**EARLY TURNIP RADISH.**—A quick-growing round sort, crisp and sweet. Sow at any time after frost is out in early Spring, and at intervals until September. If the early sowings are allowed to go to seed, a second crop may be raised from this seed the same season. It always reproduces seed the first year.

No. 95.—**HUBBARD SQUASH.**—The best Winter Squash we have tried. Keeps until Spring. Plant middle of May. Color, light bluish green, hard shell, rich, dry flesh. It is good also for Autumn use, even when cooked green.

No. 101.—**IMPROVED ORANGE CARROT.**—A fine yellow variety, suitable for the table and for stock. Sow early in May, on deep, rich soil, in rows 15 to 18 inches apart.

No. 141.—**DARLING'S EARLY SWEET CORN.**—We have tried many other sorts, but come back to this, as combining sweetness and early maturity. It is quite small in stalk and ear, and may be planted in hills or drills 2 to 2½ feet apart, unless other crops are put between the rows to occupy the ground after this is out of the way, which will be before mid-summer, if planted early. It may be planted all Summer for a succession.

No. 145.—**FLAT DUTCH CABBAGE.**—A Winter sort extensively grown for market, frequently under the name of "drumhead." The heads are large, and require to be 2 feet apart, in 2½ feet rows.

No. 147.—**NEAPOLITAN CABBAGE LETTUCE.**—A large solid sort which has proved valuable. Sow at any time in April, May, or June, covering seed lightly. Leave best plants for seed, which is produced the same season.

No. 149.—**EARLY BASSANO BEET.**—Fine quick-growing, turnip-shaped for early use. Sow in drills 1 foot apart.

No. 152.—**LARGE CHEESE PUMPKIN.**—One of the best for general culture. A large, flat, cream-colored variety, sweet, and good keeper. Plant middle of May, allowing ample space for them to run.

No. 154.—**ICE CREAM WATER MELON.**—One of the best sorts, sweet and tender. Plant in open ground about the middle of May; can be started earlier in hot-bed.

No. 186.—**STOWELL'S EVERGREEN SWEET CORN.**—A much larger variety and slower grower than No. 141, remains in the milk a long time, hence called evergreen. Good for later table use, and for fall drying. If to be ripened for seed, plant early; for table use, from May 15 to June 20, hills or drills 3½ to 4 feet apart.

No. 187.—**CONNECTICUT SEED-LEAF TOBACCO.**—One of the best for Northern culture. A thimble full of seed will furnish plants for an acre. Sow in a sheltered seed-bed about the middle of April, and plant out middle of June, on rich dry soil, 3 feet apart each way, or 3½ feet by 2 feet, to facilitate working with a horse hoe. For after treatment, see last volume of *Agriculturist*.

No. 188.—**HAVANA TOBACCO.**—Treat as No. 187, save that it requires a little less room.

No. 191.—**MAMMOTH MILLET.**—An annual, very productive in seed and foliage. Cut green it makes good

hay, or left to ripen, the straw is good, and the seed valuable for stock and poultry. Sow thinly half an inch deep, at any time in May.

No. 193.—**FEJEE, CALLED ALSO ITALIAN TOMATO.**—Large, smooth and solid, the best we have grown. Sow in hot-bed, April 1st, or 1st of May, in open ground.

No. 194.—**HOLLOW CROWN PARSNIP.**—A large, sweet variety, with a depressed crown. Sow in deep, rich soil, early in May, in rows 18 inches apart, covering lightly.

No. 195.—**EARLY SHORT HORN CARROT.**—A fine yellow variety for early table use. Sow in light soil, last of April or first of May, in drills 1 foot apart, covering lightly.

No. 196.—**GREEN CURLED KALE OR BORECOLE.**—A kind of cabbage which does not head. The whole top is boiled for greens, usually in Spring, as it bears standing out over Winter, with (and often without) a slight covering of straw or brush. Treat the same as late cabbages.

No. 197.—**LINNAEUS RHUBARB.**—Sow in deep mellow soil in April or May, covering ½ inch. Keep well hoed, and transplant the following Spring when a few stems may be pulled for cooking. A full crop can not be had until the 3d year, on which account it is better to purchase and plant roots, when they can be had. It furnishes a fine material for early sauce and pies, and should be in every garden. We have a fine lot of pure seed, as noted last month. In a few instances last year's seed sent out by us, appears to have produced new varieties that may prove even an improvement upon the original good variety itself.

No. 198.—**PURPLE EGG PLANT.**—Sow in a hot-bed, early in April, and plant out 18 inches apart, the middle of May, or after all danger of frost is over. It is still better, sown in, or transplanted into small pots, keeping them under glass until June, when they may be transferred to the soil, without disturbing the roots.

No. 199.—**RED DUTCH CABBAGE.**—Highly valued for pickling and for "cold slaw." Heads small, sugar loaf form, and solid. Set plants 15 to 18 inches apart each way. Its color is fancied by most persons.

No. 217.—**FINE NUTMEG MELON.**—One of the best sorts. May be planted in the ground after the soil becomes warm, but may be obtained much earlier if the seeds are started in a hot-bed upon pieces of soils, and these planted out in well manured hills 6 or 8 feet apart.

No. 218.—**EARLY SUGAR LOAF CABBAGE.**—We have found this to be one of the best early varieties; it forms a good sized head of excellent quality. Start in a hot bed for the earliest and in the open ground for succession.

Flower and Ornamental Seeds.

No. 23.—**MIGNONETTE (Reseda odorata).**—An annual in this climate. The flowers not conspicuous but yield a rich odor. Its habit is low, branching upon the ground; flowers profusely from midsummer until frost; sow in pots for winter blooming. A great favorite. Sow as early as the ground can be worked—the seed is long in coming up.

No. 27.—**COCKSCOMB (Celosia cristata).**—A very curious and common annual, native of the East Indies. Flowers in fantastic, irregular spikes, inclining to the fan-shape, like the comb of the cock, and of the richest crimson color. Sow in rich soil, early, and thin to 18 inches apart.

No. 30.—**TASSEL FLOWER (Cacalia coccinea).**—Called also "Venus' Paint Brush." A delicately beautiful annual, growing 1 to 2 feet high, and blossoms freely. The scarlet flowers are perfect little tassels, very bright and pretty. Sow in May, thin out or transplant to 6 or 10 inches.

No. 31.—**CHINESE PINK (Dianthus Sinensis).**—A very pretty little annual of this fine class, most of which are perennials. It is not fragrant like the Sweet William, nor does it grow in clusters. Color varies from maroon and crimson with pink edging, to white with a red center. They flower for many weeks in succession; desirable in every flower plot. Sow in early Spring. The roots frequently survive the Winter.

No. 37.—**ZINNIA, (mixed) (Zinnia elegans).**—This beautiful Mexican plant is a brilliant addition to the flower garden. It is tall, elegant and showy, with flowers of many colors, purple, crimson, orange, scarlet, violet and white. Sow middle of May, keep plants 18 inches apart.

No. 42.—**FOXGLOVE (Digitalis alba, purpurea, etc.).**—A perennial, blooming the second year from seed. The flowers are very pretty, often beautifully mottled with purple and brown spots. It blooms upon a spike 2 to 4 feet high, beginning at the bottom, and continues for several weeks. The medicine digitalis is the leaf of this plant. Sow in early Spring. The roots often die out after flowering a year or two.

No. 49.—**CANDYTUFT (Iberis umbellata, and amara).**—Suitable for massing or for borders. An annual with

clusters or umbels of small flowers, of various colors, from pure white to purple. Grows 6 to 12 inches high, and blooms most of the season. Sow early in Spring.

No. 51.—**DRUMMOND'S PHLOX** (*Phlox Drummondii*).—A very beautiful annual, the delicate flowers of which exhibit a very great variety of marking. Grows 12 to 18 inches high, requires little care, blooms constantly, and is beautiful in masses. Sow early in May.

No. 89.—**COTTON PLANT** (*Gossypium herbaceum* and *Barbadense*).—The Upland, with a little Sea Island Cotton Seed, both in the same package—the Upland downy, the Sea Island naked. The Upland, sown in the Spring, and protected from frost, will mature its bolls in the Autumn, south of 40° or 41°, but will bloom wherever corn succeeds. The plant grows 3 feet to 5 feet high; the flowers are showy—bright yellow, with purple eye. Sow at corn planting, in drills, and thin to 18 inches apart. Our parcels are designed for ornamental and small experimental plants.

No. 111.—**CASTOR OIL BEAN** (*Ricinus communis*).—A stately plant, 5 to 10 feet high, with broad tropical foliage, which is showy and beautiful. It is a very rank grower, and needs a rich, warm soil. Sow in the open ground, and leave 3 to 6 feet apart.

No. 122.—**CANTERBURY BELL** (*Campanula media*).—Showy, flowering the second year from seed, and sometimes living 3 or 4 years. They bloom along a spike 2 to 3 feet high; flowers of perfect bell shape, large, and in some varieties double; white, lilac, blue, and intermediate shades. Sow any time in May or June, and transplant in the Fall to 1 foot apart in rows, or set in groups.

No. 123.—**GILIA** (*G. nivalis*).—An annual of 1 foot in height, delicate growth, and finely divided leaves; flowers usually white, growing in panicles. Good for massing. Sow early in Spring.

No. 124.—**WHITELAVIA** (*W. grandiflora*).—This California annual pleases us much, blooming 5 to 6 weeks from sowing, and continuing until October. Its blue, bell-shaped flowers resemble the Campanulas. Sow early in May, and thin to 6 inches apart; grows 1 foot.

No. 126.—**LONG-TUBED CENTRANTHUS** (*C. macrostemon*).—An annual of rather delicate appearance, but hardy and desirable. Flowers fasciated, (in bundles or clusters), tubular, borne on stalks 10 to 12 inches high. Bloom until frost. Sow early, and thin to six inches.

No. 164.—**SWEET SCENTED AGERATUM** (*Ageratum Mexicanum*).—A pale blue or white annual, desirable for bedding or massing. The plants may be taken up in the Fall and put in the conservatory or hot-house where they will flower during the Winter. Sow early in Spring.

No. 169.—**BEAUTIFUL CLARKIA** (*Clarkia pulchella*).—A hardy Rocky Mountain annual, growing 1 foot high. Flowers, light purple, opening from June to Sept. Sow about the first of May. A good border flower.

No. 170.—**EVENING PRIMROSE** (*Oenothera biennis*, *macrocarpa*, etc.).—Fine biennials which are not sufficiently known. Most of the species are low, with light yellow flowers, some of which are 4 or 5 inches in diameter, and expand in the evening, whence the name. Sow in May and transplant in October, setting 2 feet apart. Some species have a white bloom.

No. 173.—**MIXED LARKSPURS** (*Delphinium consolida*).—Annals of white, rose, pink, blue, and variegated colors, growing from 2 to 3 feet high. Some of the species are double and very pretty. Flowers in spikes for a long time in succession. Sow very early, as the seeds lie long in the ground; they are very hardy.

No. 177.—**QUAKING GRASS** (*Briza gracilis*).—A beautiful nodding grass, growing 3 feet high. The heads or panicles resemble the rattles of the rattlesnake, and dry so as to be very ornamental in bouquets of dried flowers. Sow in early Spring.

No. 182.—**SWEET ALYSSUM** (*Alyssum maritimum*).—An annual, nearly 1 foot in height, flowering in long racemes, from June to November, or until killed by frost. Sweet-scented; flowers white. Sow in early Spring, and thin to 1 foot apart, unless massed, for which it is well suited.

No. 183.—**IMPROVED FRENCH AND GERMAN ASTERS**.—A beautiful hardy annual. The common "China Asters" give no idea of the beauty of these improved varieties, some of which are nearly as large as Dahlias, and very double. We have grown nearly half an acre for seed for distribution, though from the little seed in perfect flowers, the parcels are necessarily small. Sow in open ground in May. They bear transplanting to any desired position.

No. 200.—**FANCY GOURDS** (*Lagenaria vulgaris*, in var.)—Cultivated for the singularity or beauty of the fruit; vines climbing. Plant like cucumbers, near a trellis, or provide poles; protect against insects. Our seed consists

of all the seeds from the prize collection of 75 varieties exhibited at the recent show at the *Agriculturist* office. They were necessarily mixed for general distribution.

No. 203 and 204.—**GERMAN AND FRENCH POPPIES** (*Papaver somniferum* and *Rheas fl. pl.*).—Of these common yet very showy species there is an infinite variety in form and color. The culture is simple. Sow in beginning of Spring, thin out to several inches apart; bloom in July.

No. 205.—**DOUBLE FRENCH MARIGOLD** (*Tagetes patula*).—A very showy annual of 2 or 3 feet high; flowers bright yellow to dark brown, and often beautifully striped and margined. Sow first of May; blooms from July to frost.

No. 206.—**GOLDEN STRAW-FLOWER** (*Helichrysum bracteatum*, etc.).—One of the most common of the *immortelle* or everlasting flowers; blooms yellow, white, pink, and scarlet. Grows 2 or 3 feet high. Sow in borders in May. Pick flowers before expanded, for Winter bouquets.

No. 209.—**DWARF BLUE LARKSPUR** (*Delphinium formosum*).—A fine herbaceous perennial, blooming first season, 18 inches high; flowers ultramarine blue, very rich; blooms July to September. Sow early in May.

No. 210.—**DWARF MORNING GLORY** (*Convolvulus minor*).—A very showy annual, growing 14 to 20 inches high; the funnel-shaped flowers, blue, white and yellow. Sow early in May. Blooms from June to October.

No. 212.—**SWEET PEAS** (*Lathyrus odoratus*).—A familiar annual, valued for the remarkable sweetness and beauty of its flowers. Its habit, mode of flowering, etc., is much like the garden pea, but it is much more delicate. The flowers are of many bright colors, (red, white and blue,) beautiful in bouquets.—A great favorite. Sow early, in good soil, seeds 2 inches apart; requires brushing; grows 2 to 6 feet high.

No. 216.—**ACCROCLINTUM** (*A. roseum*).—An everlasting flower. Grows 1 to 2 feet high; flowers rose-color, very pretty. Sow middle of May, in sandy loam, or grow in pots and turn out into the open border first of June. In stiff soil, make drills, and cover lightly with sandy soil.

No. 219.—**MARTYNIA** (*M. proboscidea*, etc.).—This, sometimes called "Buffalo Horn," from the form of the pod is a vigorous annual about 2 feet high, of a spreading habit and rather coarse foliage. The flowers are shaped somewhat like those of the foxglove, of various colors and very showy. The curiously shaped fruit makes very good pickles if taken while tender. Sow in good soil after all danger of frost is over and leave the plants about 3 feet apart.

No. 220.—**NANKIN PERILLA** (*Perilla Nankinensis*).—A hardy annual cultivated for its singular foliage which is of very beautiful dark purple color, and makes a fine contrast with other flowers in the border.

No. 221.—**STRIPED MIRABILIS** (*Mirabilis Jalapa*, in var.).—The new varieties are a great improvement on the old Four o'clock. The plants grow 2 to 2½ feet high. The long fleshy roots may be taken up after the frost has cut down the plant, and preserved like Dahlias to be planted the following Spring.

No. 222.—**CONVOLVULUS VARIEGATA**.—A low twining variety remarkable for its beautifully variegated foliage. Flowers purple. Should be started in pots and put out in the ground in settled warm weather.

No. 223.—**MOURNING BRIDE** (*Scabiosa atropurpurea*).—A hardy perennial which blooms the first year, if planted early. Leaves divided; flowers dark crimson purple, rose-colored and white.

Death of a Prominent Agriculturist.

Our foreign exchanges bring the mournful news of the death of Mr. Jonas Webb, of Babraham, England, whose name has so often appeared in these columns as one of the most noted and successful breeders of stock, particularly of South-Down sheep. For forty years Mr. Webb made the improvement of these animals a constant subject of study and experiment, and by his skill raised his flock to a grade that gave them a world-wide reputation. America and Europe acknowledge him as a public benefactor. His success in improving sheep has given additional value to whole provinces. It was our good fortune to enjoy several pleasant chats with him at the Royal Agricultural Show in London last Summer. We found him daily at his post, describing the merits of his four magnificent Short-Horn cows, on the good points of which he was all enthusiasm. His tent was the center of attraction to multitudes of stock breeders from all parts of Europe. Mr. Webb was 66 years old on the day of his decease. The circumstances attending it were particularly painful. The death of his wife was an overwhelming blow, under which he sank on the evening of her funeral, and on the day set apart for the marriage of his son.

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

No More Premium Maps.—Letters continue to come in daily, asking for premium Maps. Our offer was distinctly limited to the end of November. We stated in the December *Agriculturist*, that owing to the increased cost of our own paper, and the higher price of the Maps, we could no longer afford this premium, though we have continued to send them when asked for by those living too remote to apply before the close of November. We repeat, that except in special cases, and for strong special reasons, no more Maps can be given. The price is 25 cents each for the large map of Virginia and that of the Southern States, and 50 cents for the map of the United States, including the Canadas and New Brunswick. When desired at these rates, we will procure and send them post paid by mail.

Premiums—Last Call (?) We publish our premium list in full this month, probably for the last time, though all the offers will be continued until further notice—how long we can not exactly tell, as it will depend upon the future price of printing paper. Those who wish to get any of our valuable premiums will do well to set about it at once. There is yet time to fill up the lists already commenced and to start new ones. A good article can be easily obtained now, without outlay of money.—N.B. It will be seen, that the terms of two or three articles are slightly changed, owing to the advance in their market price.

Fruit Grower's Meeting—Change of Hour.—The time of meeting on Thursday of each week will hereafter be at one o'clock P. M. These meetings will be found the source of much valuable information. Leading practical growers are always present to describe the best kinds of fruits, the modes of planting, culture, etc., with other topics of interest relating to the orchard, garden, etc. All interested are invited to attend.

Buy your Books now.—Like everything else depending upon the price of paper (except the *Agriculturist*) the prices of books have advanced from 25 to 50 per cent. Anticipating this rise, we laid in a partial stock of those most called for from our office, and these stand at the old price in our list on page 30. Persons wishing any of these books will do well to apply for them at once, as our price list must be advanced to that of the publishers, as soon as the present supply runs out. It will be seen, that a few books in our list are already advanced a little. Persons calling for premium books will please note the changes from time to time, as we must be governed by the rates announced each month.

Honest Postmasters.—Almost every day we get letters containing subscription money, but unsealed, some of them from California even. We are happy to announce the safe arrival of so many such letters, but would advise, for the sake of keeping Postmasters honest, and especially when gold dollars are enclosed which might drop out in the mail bags, that all money letters be securely sealed.

Town Hedges.—J. W. Bucher, Northumberland Co., Pa. If to turn cattle, use heavy Locust or Buckthorn. For a screen simply, we prefer the Arbor Vitæ. In both cases it is advisable to buy plants from nurserymen or hedge-plant growers, who sell them cheaply by the 100 or 1,000. The American Arbor Vitæ is best for quick growth and cutting to any desired form. The Siberian variety grows slowly in neat, cone-like form, and is beautiful when planted singly or in close rows to form a compact screen or hedge.

"Agriculturist" Wanted.—William Beal, Lenawee Co., Mich., writes that one of his neighbors who takes no agricultural paper, recently sold a flock of sheep enough below their value to have paid for the *Agriculturist* the remainder of his life. He was not "posted" as to the market. The reading of a single article in our number for November, would have saved him all his loss. This is a sample of many similar testimonials recently received.

To Advertisers.—One who has advertised his business very extensively in most parts of the country, writes that, "the *American Agriculturist* did me as much good as all the other papers together."

Small-pox in Sheep.—This is reported to have been quite prevalent of late in England, and to prove the efficacy of vaccination, the Government has purchased 200 sheep to experiment with. They propose inoculating a portion of them with the virus direct from the cow.

Poultry Profitable.—Mr. R. W. Davey, of Middlesex Co., Mass., in a letter to the *American Agriculturist*, says he finds it pays well to give poultry warm quarters with plenty of feed. He reports the cost of keeping six fowls 11 months, from January 1st, to December 1st at \$6.04. The returns were: 551 eggs at 16½c. per doz. \$7.66. Poultry sold, \$4.70. Fowls added to stock, \$1.50; total \$13.86—a net profit of \$7.82, or more than \$1.25 for each fowl. This is certainly a very good showing on a small scale. Mr. D. justly attributes this success to the care bestowed upon his poultry; which he does not include in reckoning the cost.

The Hens Do Lay.—"A Constant Reader" writes: "I have 21 hens, good layers, but they entirely ceased giving eggs in the latter part of Summer. Acting upon a hint in my *American Agriculturist*, on Oct. 1st, I sent to the soap-fat triers, and got a 50 pound cake of scraps at one cent per pound, and placed it in a clean corner of the barn-yard. The hens, though abundantly supplied with grain, pitched into the scrap cake as eagerly as a boy would into a pound cake, though they found it hard work to get off much of the substance until after a rain had soaked it. Two weeks after, the eggs began to be dropped, and now how they do lay! We have kept no account, but we must have got a dozen and a half a day for some time, as we have consumed all we could get in the family, and have sold a surplus of 10 dozen at the rate of five for a shilling, or \$3, which I enclose herewith for three copies of the paper for myself and two friends, as named below. The eggs eaten at home more than paid for the meat (not yet half gone) and the other feed."

How Much Grain for Fowls?—C. N. Bement, writes to the *American Agriculturist*, that he has ascertained by actual experiment, that in the months of December, January and February, a common sized fowl will consume on an average one gill per day of corn, barley, or buckwheat, if permitted to take it at pleasure.

Fowls Changing Color.—E. P. Berrian, Westchester Co., N. Y., writes that he has a 2-year old black Spanish hen, which was originally a jet black, but during the last six months she has been changing her coat, and is now almost entirely white. He asks the *Agriculturist* readers to account for the phenomenon.

Age of Poultry.—C. N. Bement, writes to the *American Agriculturist*, as follows: "It is easy to judge of the age of a plucked fowl by the state of the legs. If a hen's spur is hard and the scales on the legs rough, she is old. Examine the head also. If the under bill is so stiff that it can not be bent down, and the comb is thick and rough, leave her, no matter how fat or plump, unless a tough case is preferred. A young hen has only the rudiments of spurs, the scales on the legs smooth, glossy, and fresh-looking, whatever the color may be; the claws tender and short, the nails sharp, the under bill soft, and the comb thin and smooth.—An old goose when alive, is known by the rough legs, the strength of the wings, particularly at the plutions, the thickness and strength of the bill, and the fineness of the feathers; and when plucked, by the legs, the skin under the wings, by the pinions and bill, and the coarseness of the skin. Ducks are distinguished by the same means, with this additional mark, that a duckling's bill is much longer in proportion to the breadth of its head, than the bill of an old duck."

Oyster Shells for Poultry.—H. A. Slater, Hartford Co., Conn. These broken fine are as good or better than slaked lime; they answer in part for gravel, as well as lime.

Thanksgiving Turkey Sacrificed.—A subscriber (Pliny N. Ward), of Worcester Co., Mass., in renewing his subscription to the *American Agriculturist* for 1863, writes: "...I know of no agricultural publication equal to yours in several respects. Its rich vein of sound, practical, common sense, causes its perusal to do good like a medicine; and I should wish for its monthly visits if I did not own a single foot of land, for its moral and religious influence. You will believe my statement above, when I assure you that, our Thanksgiving Turkey was sold to obtain the dollar herein forwarded." [Such kind appreciation, and this letter is only a sample of many, is certainly a strong stimulus to increased effort on the part of the Editors.]

"Egyptian Sorgho or Imphoe."—M. Beck, writes to the *Agriculturist* from Wayne Co., O., that he planted 17 rods of what was called Egyptian sorgho there, on a rich clay soil, rows two feet apart, and

canes 4 to 5 inches distant, which grew luxuriantly and ripened in October. The juice evaporated on Cook's pan, yielded 40 gallons as fine syrup as he ever saw. This was at the rate of 375 gallons per acre.

Barley—Weight of a Bushel in Me.—On page 375 of December *Agriculturist*, the weight of barley given at 56 lbs., is a typographical error; it should have been 46 lbs.

Prolific Bean.—S. G. Willard, Windham Co., Conn., says, a subscriber to the *American Agriculturist* in that County raised 326 merchantable beans of a large, white, running sort, from one seed trained on a pole 5 feet high. He thinks the "*Agriculturist* did it."

Northern Cotton—Specimens lately Received.—Ten pounds of Upland, well grown, but rather short staple, from Rev. J. A. Bent, Washington Co., Ill.—Small samples from 6 pounds of two varieties, grown by G. D. Furber, Macoupin Co., Ill., from seed sent out by the *Agriculturist*. Both of these (Upland and Sea Island,) are well-grown and fine.—Specimen long staple from H. Davison, Defiance Co., O., grown from Alabama seed, which proved too late for that climate.—Also specimen of short staple, fine fiber, from J. G. Stackpole, Meigs Co., O., from plants growing five feet high.

Silk in Ohio.—From the Census report of 1860, we learn that 2,166 pounds of cocoons were produced in Ohio that year. Michigan comes next, that State being credited with 1,043 pounds. Correspondents who have frequently asked where they can obtain eggs, will doubtless find them by addressing prominent agriculturists in those States.

Tree Cotton Seed.—Mrs. B. Davis, Ash-tabula Co., O. There is none of this seed that we know of, to be had in this country. The parties who set forth the wonderful merits of the plant a few months since, proved unreliable, disappointing many parties who had paid money for the seed.

Sweet Potatoes Profitable at the North.—Several years of experience, always successful, and a great many reports from those who followed our advice last Spring, and tried them, fully confirm the belief that it pays well to cultivate at least a small plot of sweet potatoes for home use, in any garden south of latitude 42°, where a light warm soil can be had, and even further North in favorable localities.

Cesspool Slops.—W. Gilbert, N. Y. Cesspool slops are among the most valuable, especially if the chamber slops are added, or water closet pipes enter into the cesspool. Clean out frequently, mixing the contents with muck, and a rich compost will be formed.

Salt Preserves Timber.—Asa M. Holt, Middlesex Co., Conn., writes to the *Agriculturist* that he built an out-cellar in 1828, covering the roof with sawed chestnut timber laid from the ridge pole down over the rafters. Upon this was put three feet of earth, with an outer roof of pine boards to turn rain. The roof lasted ten years, and then fell in. He then had a similar roof put on by the original builder, but before covering with earth, a bushel or more of coarse salt was sown over the timber roof. This last roof has been on 24 years, and bids fair to last some time longer.

Hardy Apples in Minnesota.—H. D. Ives, Napello Co., Iowa, referring to an item with the above head on page 288, August *Agriculturist*, says the Roxbury Russet bursts its bark in their prairie soil, and is tender beside. The same is true of the Baldwin and R. I. Greening, though in a less degree.

Vicar's Improving.—"Don't touch the Vicar's," was the advice of an old woman who has sold pears in Washington Market for the past ten years, to a person about negotiating for some of this variety. "They won't sell," added she. True, as ordinarily grown and ripened, they are uninviting to sight or palate, but as offered at the *Agriculturist* Fruit Growers' Meeting, they were really good. The secret lies just here. Thin the fruit while growing, pick late in the season, handling with care. A little frost don't hurt them. Put in a barn or other building for a week, to sweat, then take to a cool cellar, and if packed in cut hay, oats, or oat chaff, all the better. Two weeks before wanted, bring them to a warm room—say 65° to 75°—and they will often color up finely, and if they are not No. 1, they are more than good, at a time when very few pears of any kind are to be had.

Ignoramus Quince.—Such is the label on a very fine specimen of pear quince on the *Agriculturist* tables, which has a history. A progressive farmer in New-Jersey asked his neighbor why he was cutting

down his quince trees. The reply was, they were worthless, and he could not succeed in raising quinces. Our friend advised him to take the *American Agriculturist*, where he had seen good directions for growing quinces. But he did not want any "book fudge." "I left him, but took away a few twigs of his quince trees, cut from the brush heap, and treating the cuttings and the trees they produced according to the directions given by 'book fudge,' I now have as fine healthy trees as one could wish, from which I picked the specimen here sent, and some 60 other fine quinces. I have shown the trees and fruit to 'Ignoramus,' and if he don't come down with the dollar, I think he will get a present."

Prune the Grape Vines Now.—Don't leave them so late that the pressing sap in the Spring will force its way through the partially hardened cut. We much prefer November and December, or at latest, January for the annual trimming. Prune judiciously, cutting out to within one eye, the last bearing cane or shoot, where the renewal system is followed, and taking out a portion of the old wood of old vines allowed to ramble over an extensive trellis, or on the side of a building. The new growth should also be shortened in somewhat, bearing in mind, however, that this is to be the next fruiting wood.

Delaware Grafts.—J. Borland, Bucks Co., Pa., in a letter read at the *Agriculturist* Fruit Growers' Meeting, says he raised Delaware grapes from grafts inserted in old roots. He advises laying an old vine in a trench early in Spring, and graft by splitting it at intervals, and running the wedge of an ordinary graft perpendicularly through this split; then cover with 3 to 4 inches of earth, leaving one bud out of ground.

What Grapes to Plant.—This is a puzzling question to the amateur, even, and much more so to a novice. In order to settle the question, the Fruit Growers' Meeting have appointed a judicious committee to bring in lists, from which, after discussion, probably for weeks, a selection will be made and adopted as the Society's list.

Grafting Large Plum Stocks with Apricots.—J. Webster, Marion Co., Ill. Better graft in the branches, if the trees are three inches through. Small seedlings of one or two years' growth are best budded close to the ground.

"A Pomological Congress of Nations" is announced in the *Revue Horticole* to be held at Namur, Belgium, Sept. 28, 1863, to which delegates are invited from all countries. The special object is to form a standard nomenclature, which will prevent a great deal of confusion, and not a little loss, especially to our own nurserymen and fruit growers, who often import, at a heavy expense, what they already have growing under another name.

Fruit Growers' Magazine.—E. Newberry, Evansville, Ind. There is no periodical in this country devoted wholly to fruit growing, and none giving more space to this subject than the *Agriculturist*.

Good Currants.—A. A. Davison, Mason Co., Ill., says he picked 128 quarts of Red Dutch currants from 33 bushes, some of which were too young to bear a full crop. The older ones bore 6 to 8 quarts per plant.—From one three-year old Houghton's Seedling Gooseberry bush he picked 3 quarts of fruit. This will do for a beginning, but a much larger yield may be looked for.

Brush for Scraping Trees.—We have lately seen a brush made of metal instead of hair, for cleaning trees of moss and dead bark. It is a French device, which Yankee ingenuity could improve upon. But a house broom, cut off to a stub, answers very well. Follow this up with some alkaline wash.

Fruit Talk 280 Years Ago.—"The names of apples which I had their graffics from Brintenarch, from one Mr. Pace: Item, the apple out of Essex; the Lether-cot or Russet apple; the London pippin; the Ken gnerling, or the Croke; the glass apple or pearmain; the red stear; the Nemes apple or grenling; the Bellebone; the apple out of Dorshetsher; the Domine quo vadis; the Paces pear," etc. etc. (Extract from the Common Place book of John Trevelyan, of Somersetshire, 1582.)

Flowers from Vermont.—Miss A. M. Allen, Lamoiile Co., Vt. Your "*Eupatorium*" is *Veronica Virginica*. "*Fall Crocus*" is *Colchicum autumnale*, or meadow Saffron, while the bulbous rooted flower proves to be *Ornithogalum umbellatum* or Star of Bethlehem. The white flower is probably *Achillea Ptarmica*. "*Siberian Ash*" is *Pyrus Americana*, and "*Lady of the Lake*" we judge from the specimen to be *Physostegia Virginiana*.

Keeping Butter.—George W. Pomeroy, Montgomery Co., Pa., says he tried the recipe of D. E. Smith, given by a subscriber in the *Agriculturist* on page 138 of last volume (May No.) and injured his butter thereby. The recipe says: "Work May or June butter two or three times, adding at last working one grain saltpeter and a teaspoonful loaf sugar to each pound of butter. Pack in stone jars to within two inches of top, and fill with strong brine, cover tightly and bury in a cellar bottom." Has any one else tried it?

Steamed Carrots for Cows.—M. S. Wickersham, Philadelphia, Pa., writes to the *American Agriculturist*, that his cow has improved in yield of milk since commencing to feed steamed in place of raw Carrots. We believe cooked roots to be best for feeding; the question not yet fully decided is, whether the cost and additional labor will be repaid by increased thrift of the animal.

Sawdust in Stables.—Rhode Island will find by referring to volume 18, page 357 (1859) of the *Agriculturist*, that his suggestion is not a new one. We are glad to receive his testimony, that it makes a clean and comfortable bed and greatly increases the value of the manure by absorbing the liquids.

No Use for Manure.—J. H. Hayes, Carroll Co., Ind., writes to the *American Agriculturist*, that its teachings on the general use of manures are valueless in that region, because the land is already rich enough to yield 80 bushels of corn and 25 to 40 bushels of wheat per acre. Just so it was once on thousands of acres in Virginia, where now the land will scarcely bear the shadow of grain. Manure is needed at the West, to keep the land good. It is true that not so much will be required, as where by neglect of manuring the soil has become sterile; but sooner or later all land not fed will grow lean, and so will its owners' pockets.

Flowing Swamp Land.—H. G. Chamberlin. Land covered with muck, like yours, will not be benefited by flowing, unless it is planted with cranberries. It would injure the tame grasses of mowing lands to allow water to stand on them for a few days even. Cranberry lands may profitably be covered with 6 inches of water from the middle of Nov. to the middle of April.

Sorghum Seed.—Wm. Fulke complains, as do many others, of the difficulty of procuring good seed. Sorghum and its allies are merely sweet varieties of the common Broom Corn, just as Sweet Corn is a variety of Indian Corn, and, like that, is liable to lose its peculiarity or "run out." Experiments are needed to determine the mode of cultivation which shall perpetuate or even improve the variety. Here is a useful and profitable field for some one, for we cannot afford to import our seed each year. Who will try?

American Jute.—This name has been given to a fibre prepared by a process patented by W. S. Cantelo, from the *Hibiscus Moscheutos*, or Swamp Rose Mallow. The plant grows native on our salt marshes or river banks near the coast, and around salt springs. It throws up numerous stout stems 4 or 5 feet high, which bear large rose-colored flowers, much like those of a single Holyhock. It belongs to the Mallow family, the plants of which are remarkable for their tough bark. The Cotton plant belongs to the same family. It is claimed that three and a half tons of fibre, fit for manufacturing paper, and worth \$100 per ton, can be raised from an acre. Should this statement be only partially true, much land that is now unprofitable could be devoted to its culture.

Materials for Making Paper.—The scarcity of Paper stock has led to experiments upon various vegetable fibers, some of which we have noticed in other items. The fiber of the wood of the Linden, or common Basswood, has been for some time successfully used. A patent has recently been obtained for making Paper from corn husks. The common Life Everlasting (*Guaphalium polyccephalum*) has been converted into tolerable Paper, and we notice that in England the common "Eel-grass," (*Zostera marina*) is proposed as a material for the same purpose. This latter is found abundantly along the coast, and is often incorrectly called Seaweed, the latter being an entirely different plant. It is used to some extent to fill mattresses, cushions, etc.

A Troublesome Weed.—W. M. B. Tippecanoe Co., Ind., should have sent a specimen of the plant which causes so much trouble. It cannot be the common Wild Morning Glory, which grows in low, moist ground, and which we never have seen disposed to

encroach upon cultivated land. Perhaps the plant is the European Bind Weed, having a perennial, creeping root by which it spreads rapidly. It is a mistake to suppose that particular weeds can be killed by some specific application, as that which will destroy weeds will also kill useful plants. Like other evils, prevention is easier than cure. The most obstinate weeds are easily eradicated when young, but when they once get possession of the soil, the task becomes very difficult.

The Cultivation of Peppermint.—"A Subscriber," Butler Co., Iowa, thinks Peppermint might be cultivated with profit, if there were a regular and steady demand for the oil. The plant has been profitably cultivated in St. Joseph Co., Michigan, which has during the last ten years produced the largest portion of the Oil of Peppermint used in the world. Not only our own country, but Europe has been largely supplied from this quarter. The product varies greatly in different seasons, and the price fluctuates accordingly. The amount of Oil produced per acre ranges from 7 to 20 pounds, and the price from \$1.25 to \$4.00 per pound.

A detailed account of its culture may be found in the proceedings of the American Pharmaceutical Association for 1858.

California Milkweed.—T. J. D. sends us from Sacramento the pods of a species of Milkweed, (*Asclepias*) suggesting that it may be useful to paper-makers. In the absence of leaves, we are unable to identify the species, but the pod much resembles that of the common milkweed, *Asclepias incarnata*. The hairs or down upon the seeds of the various species of Milkweed are among the articles which have been proposed as a substitute for the ordinary kinds of paper stock. We are not aware that any experiments have been tried with it, but doubt whether it has sufficient strength of fiber.

Ginger Root—To Several Inquirers:—Ginger is a tender plant and will not stand our winters, though it may be grown in the open ground, by taking it into the Green-House during Winter, and giving it plenty of water.

"Live for Ever."—*Sedum Telephium*.—This plant, known also as Orpine and Aaron's Rod, is reported by a subscriber in Connecticut, to become a troublesome weed in some localities. If any of our readers have had any experience in exterminating it we shall be glad to hear from them.

Propagating from Diseased Trees.—F. G. Wilson, New London Co., Conn. Experienced nurserymen object to propagating by grafting with cions from diseased trees.

Trees vs. Flowers.—It must be acknowledged that tree-planting has this superiority over the making of flower gardens, that the former is designed chiefly for the benefit of a succeeding generation, while the latter is for our immediate personal gratification.

Euonymus.—How to Propagate.—From Fulson, Rockingham Co., N. H. The *Euonymus atropurpureus*, called the Burning Bush, and at the West the Wahoo, is one of the finest of our native shrubs, being very brilliant in autumn, when covered with its scarlet fruit. It is raised both from seeds (to be had of seedsmen), and by cuttings or layers. Plants of this as well as of the European varieties can be had of nurserymen at 25 to 50 cents each.

To Enjoy Your Garden.—Keep within your means: both in respect to the size of it, and the labor, time and cost of keeping it in good order. There is a great deal of enjoyment in snugness.

A Fragrant Fancy.—A highfalutin correspondent of a certain paper, writing from his garden-bower, says: "The *Chionanthus fragrans* has been, for the last six weeks, covered with expanded blossoms in our shrubby border. It blooms best as a standard bush. The fragrance not only perfumes the garden, but all the neighborhood; and in the direction of the wind, (a gentleman informed me,) it may be smelt half a mile off! At certain seasons, when this and a few other plants are in flower, a stranger may literally smell his way to my garden!" Whew!

To Make a Garden Roller.—"Mary," Vergennes, Vt. A pretty good home-made roller can be constructed as follows: Take a straight log from the forest, say 2 feet through, and 1½ to 2 feet long, the ends sawed off square; remove the bark, and fasten into a frame by means of iron pins in the center of each end.

This will answer for the lawn or gravel walk. They are sometimes made by nailing narrow planks upon circular end pieces, the edges rounded off to make a smooth circular surface, and a box of stones or other weight fitted on top. If of pine or other light wood, the roller can be made larger in diameter, so as to roll more easily without being too heavy for hand use.

Double Crocus.—In reply to the queries of "Horticola," and our own comments in the November No., T. J. James, M. D., of Rochester, sends to Horticola, through us, a neat box containing flowers of the double Autumnal crocus. We understood Horticola as referring especially to the Spring crocus, but the Autumnal is very beautiful and rare.

Case-Knife and Lima Beans.—Wm. R. Davey, Mass., asks whether the Case-Knife Beans can be improved by planting the large Lima among them. Most of the ordinary Beans are varieties of the same species, and will cross and mix freely, while the Lima is a distinct species, and will not do so. As the large Lima does not succeed in his locality, we recommend him to try the small Lima; by starting them in a frame upon pieces of sod, and not planting out until settled warm weather, they have succeeded in a much colder locality than Massachusetts.

Chili Potatoes.—Large Yield.—Geo. Nichols, of Madison Co., N. Y., writes that he obtained from 4 "Chili Potatoes" a yield of 42 lbs., probably refers to the "Garnet Chili." They were cut into pieces with two eyes each, and planted without any unusual preparation of the soil. We have had two years' experience with this very productive variety, but found it always hollow in the centre. Have others found similar trouble?

Big Bassano Beet.—Isaac Beemer, of Litchfield, N. J., reports fine success with this variety of Beet from seeds received from the office of the *Agriculturist*. One of his specimens measured 26 inches in circumference, and asks if any one can beat that Beet. He recommends planting in a seed-bed, and transplanting, and thinks it is not generally known that Beets may be as readily transplanted as cabbage.

Topping or Facing.—"C. C.," of Jamesburg, N. J., says we must not spare the "little sins," as some are inclined to call the deception used in "topping" or "facing," apples, potatoes, etc. He regrets that the practice has become so common, that words are even coined to express it, and thinks that the corruption in government even may be traced back to such beginnings. We recently saw a striking instance. A very poor lame man had managed to get together money enough to buy a basket of apples to peddle. He took the basket from a barge at the wharf, brought it upon his back with much exertion for him, and sat down near our door to commence business. The first two layers were fine fair apples, but all below them were hard, gnarly specimens that a pig would squeal over. Instead of making a profit, the poor man lost half of all the money he had in the world. That was at least one degree below stealing.

Parasites.—Those plants which live upon the juices of other plants, are of two kinds: Those which take the crude or ascending sap, and those which live upon the elaborated or descending sap. The former receive the crude sap and elaborate it in their own green leaves, and can, like the Mistletoe, live upon widely different plants, while the others, living on material already prepared for them, are without green foliage, and, like the Beech Drops, are always found on the same or closely related species.

Sweet Potatoes for Coffee.—E. Stillwell, of Monmouth Co., N. J., sends us a sample of Sweet Potatoes prepared for Coffee according to the following directions: "Wash the potatoes clean, cut into thin slices, dry in the sun or an oven, and then roast the same as coffee. For 12 persons, take ½ cup of ground coffee, and ¾ cup of roasted potatoes not ground but left in slices, and add water in the usual manner." We tried the sample as directed, and find it of fair quality, but having a little more coffee taste than the mixture of rye and coffee more common in the market. The potatoes may have been roasted a little too much in this instance. Potatoes too small for ordinary cooking can be used thus.

Extract of Flesh, or Solidified Beef Tea.—This article is recommended not only for use in hospitals, but as a concentrated and readily portable food for soldiers. It is prepared by chopping beef, free from fat and bones, as if for sausage meat, and mixing it with its own weight of cold water. It is then slowly heated to

boiling, and allowed to boil one or two minutes. The liquid portion obtained by squeezing in a cotton cloth, is then evaporated to dryness. The evaporation should be done carefully, by placing the vessel in another larger one containing hot water. Half an ounce of this extract represents a pound of fresh beef, and when dissolved in a pint of water, makes a strong and nourishing soup. People at the West, where beef is so cheap, can readily prepare a valuable nutriment for their friends in the army.

Designating Nails—Why "Penny?"

—"L. F. P.," inquires of the *Agriculturist*, why common nails are designated sixpenny, eightpenny, etc.—The word *penny* appears to be a corruption of the word *pound*. Nails were counted by the six score (120), and by the great score or 1200. Sixpenny nails were those of a size to weigh six pounds to the 1200; tennepenny nails those weighing ten pounds to the 1200; and so of other sizes.

Book on Skeletonizing Plants.—

This beautiful art has been several times referred to in the *American Agriculturist*, and some illustrations have been given with a brief description. It consists mainly in preparing leaves and capsules of plants so as to retain the delicate veins and fibrous tissue perfect, but bleached white. Many of the specimens equal in beauty the most exquisite tracery in marble. The essential part of the process is, to place the leaves, etc., in warm water, and then let them lie in the same place for several weeks until the skin and cellular tissue decay so that they can be removed with a soft brush. The skeleton is then bleached in a weak solution of chloride of lime or other bleaching preparation. The art may well be practiced by every lady at very little outlay of time or expense; the specimens obtained are far more beautiful than the most elaborate ornaments that can be worked with the needle.—We have received from the Publishers (Messrs. Lippincott & Co., Phila.,) a little volume of 50 pages from the pen of Dr. Parish, called the "*Phantom Bouquet*," describing the process particularly and giving some exquisite engravings of prepared leaves. The paper, press work, and illustrations are admirable. It may be had at this Office. Price \$1, (which includes postage when sent by mail).

Agricultural College of Penn.—A

pamphlet of 63 octavo pages giving a succinct history of Agricultural Colleges generally, and of this one in particular, has been sent us by Dr. Pugh, the President of the College. It opens with the origin of agricultural education in Europe, by briefly tracing its history to the present time; it notices the several attempts to found agricultural colleges in this country, but is mainly devoted to the history of the Agricultural College of Pennsylvania.—This Institution has been full during the session just closed—110 students having been in attendance. The large and commodious buildings of the college about being completed, at an expense of over \$100,000, will be ready for students next year. The next session opens on February 22. Persons wishing further particulars can address Dr. E. Pugh, Agricultural College P. O., Center Co., Pa.

The Basket Overflowing.—Our correspondents will please have patience. The paper is full, and we still have a large number of good basket items, as well as other articles which must wait for room.

Our Seed Distribution for 1863.

On page 4 is a list of seeds offered to our readers this year together with the method of distribution. The design of the annual distribution is simply this: With our special facilities for raising and purchasing good seeds, and by a wholesale system of operations, we are able to put up and send out, at an expense comparatively small for each subscriber, though large in the aggregate, a few parcels of choice seeds, either new or specially valuable, which may serve as germs to future abundance in each locality where they are grown. Most of the seeds are annuals, and will therefore multiply rapidly. A single plant of some varieties will yield seed enough for two or three plots another year, and by the next year the single original seed may supply a dozen or more neighbors.—Our aim is not to furnish a seed store for those accessible to good seeds and able to buy them, but rather by the free presentation of a few seeds where they would not, or could not be purchased, to awaken a taste for experiments, and for the cultivation of beautiful and useful plants. We introduce seeds of many common kinds, mainly for the benefit of those living remote from any access to good seeds, to whom they will prove acceptable. Most persons, however, will find in the list some seeds they have not yet met with or at least have not tried.

Explanations.—We regret to make the list of seeds

smaller than it has been in past years, or is likely to be in the future, and also to limit the parcels to only three or four. Nor can we introduce a large number of new seeds intended for this year, for the following reasons: First, the enormous rise in the cost of printing paper, (see page 32) leaves us no margin of profit for seed expenses. 2d. Several plots of seeds we were raising specially for distribution turned out badly. For example, we sowed four acres of an imported heavy oat, intending to make a specially large distribution of the seed. They were promising finely, but just before filling out, a furious wind and rain storm prostrated and literally destroyed the whole crop. 3d. While in Europe, we arranged with several parties to order from them, if desired, an unusually large supply of extra fine seeds of many new kinds. But the duty of 30 per cent added to imported seeds, with the thirty odd per cent premium upon the money in which the duty must be paid, the advance of foreign exchange to 145 and 150, and other increased expenses of importation will double the first cost which is very high for such choice seeds. We should have endured even this, however, had not the greatly increased cost of our paper rendered it impracticable, without raising the subscription price, a thing we do not wish to do.

With these explanations, we present the list, hoping that it will be more than acceptable to our readers. The supply of several kinds is limited, but we will do the best we can under the circumstances, begging the indulgence of our readers if we are unable to do all they would desire.

What our Agricultural Bureau ought to Do.

When the new Agricultural Bureau was provided for by Act of Congress, we had some hopes that good would come out of it. That the General Government should do something—should do much—to foster and develop the greatest interest of our country, its agriculture, is too evident to require argument. That no change for the worse could be made upon the system pursued during several years past, seems almost equally evident. The appointment of a head to the new department being a matter of so much importance, we tried to indicate to the President that in the selection of the Commissioner he should not be guided by his kind hearted feelings, by family considerations, or by importunity, but appoint the best man, the one of the most comprehensive views, of activity, experience, administrative talent, and enterprise. How far he was guided by such considerations we do not pretend to say. The appointment being made, we determined to judge of it by the result produced. So far we have waited and are still waiting to see what will be done. Any real good accomplished we stand ready to approve. Whatever hints we may offer to the gentlemen in charge of the Bureau, are therefore given in the kindest spirit. The Department belongs to us, in common with every other person interested in the agriculture of the country.

What ought it to do? First, we say, that it should aim at investigation, at the collection of information and statistics which can not be attempted by individuals. To illustrate: The distribution of seeds, excepting those of rare and costly character, can be done by individuals. Our Agricultural Department at Washington, has been mainly a free government seed store, largely devoted to collecting, at public expense, a great number of seeds, mostly common, and of good, bad, and indifferent quality. These, together with an annual volume of little value, have been distributed at random by members of Congress as political instrumentalities. It is well for the Government Bureau to collect rare and new seeds from other countries, and test their utility in different parts of our own country. But this should be only incidental.

Here are a few of the things we would pro-

pose for the attention of the Agricultural Bureau:

I.—The opening of a comprehensive and systematic correspondence with leading, reliable, and intelligent cultivators, at least one in each county in the United States, after the plan of M'Killop's commercial agency in this city. At that agency one can learn, on the instant, the exact status, the financial condition of any business man in the entire country. Such a system of government correspondence would enable the Agricultural Bureau to gather prompt information on any topic of general interest.

II.—The collection of accurate early information from the whole country in regard to the amount, condition and prospects of the growing crops. This information to be gathered frequently during the growing season, say from May to September, and the general result to be published for the guidance of both farmers and commercial men, and to be given to the public at once—not a year afterwards when of no particular value. The special announcement by telegraph, that "full returns to the Agricultural Bureau indicate a given amount of wheat or corn growing, and that the prospects at a given date indicated an average or a deficient or a surplus yield," would be hailed by all classes as something tangible and useful.

III.—A thorough discussion, founded on comprehensive and general information, of two or three leading crops, each year. To illustrate: Grass, or the forage crop, is the most important one of the country. Could not the Bureau of Agriculture, with its facilities, set on foot and carry out an investigation which would tell us definitely: what are the peculiar characteristics of the Blue Grass regions of Kentucky, and into what other portions of the country that grass might be introduced with advantage; what kind of grass proves to be the best for prairie soils in the different localities, and why; and the same of clay soils, loams, bottom lands, etc., in the various climates, and at different elevations; the relative value of timothy, clover, lucerne, red-top, etc., for growing cattle, working animals, dairy purposes, also for horses, sheep, etc. The information should not be an Essay for the Report, at so many dollars per column, by one man, founded on his own limited observation, but it should embrace the results of a collection of reliable information from the whole country. Let the whole force of the Department be concentrated upon one, two, or three crops a year, according to its facilities for doing it thoroughly.

IV.—The introduction and testing of new seeds and plants. The present system is wholly wrong. It is worse than useless to collect a great mass of seeds, and scatter them broadcast over the land, at the caprice of Congressmen who use them at random as electioneering or political appliances. Let the Department secure a moderate supply of several new seeds and put a portion into the hands of a few persons of known skill and enterprise, in a sufficient number of localities to make the experiment general for the whole country, and let careful returns of the results be obtained and published. A hundred parcels of seed thus tested, would furnish more information than a million parcels scattered promiscuously. One or two hundred specimens of a new plant thoroughly tried in as many localities, would be amply sufficient to test its value, and the results obtained from their careful trial in judicious hands, and under specific instructions, would be decisive.

The above are a few suggestions we would offer to the managers of the new Bureau of Agriculture. We may add others hereafter.

END OF THE LAWSUIT-DIVISION OF THE PROPERTY.

(Designed and Engraved for the American Agriculturist.)

The above sketch by our German artist, A. Hochstein, is designed as a sequel to the picture of last month, in which two litigants were tugging with all their might, the one at the horns and the other at the tail of a cow, while a lawyer was quietly seated upon a pile of books, drawing his fees (milk.) We have here the final result of the suit. The cow is wasted, her flesh has gone into the milk pail—and the milk has been required to sustain judges, lawyers, sheriffs, jurors, witnesses, etc. The contestants are unusually lucky if they have not wasted the value of half a dozen other cows, to say nothing of loss of time and strength. The original cause of the lawsuit was, or might have been, (for we have known of just such a case,) a difference of recollection as to whether the cow was sold to “come in” about the first of May, or after that date, the purchaser refusing to pay without a reduction of \$3 for loss of milk during eight weeks. The illustration is not aimed at the legal profession *per se*, for we are free to say that it is an honorable one, when honored by its members. Below we give place to one of several protests from the profession, which spiritedly, and in the main justly, sets forth its value, importance, and dignity, and we need add nothing more on that point. The writer admits the prevalence of just what our illustrations are intended to discourage, viz.: a propensity to run into litigation about every real or fancied difference of opinion concerning property rights. We recommend our legal friends who protest so strongly against our last month’s engraving, to read the article appearing with the original illustration in the September *Agriculturist*, 1859, (vol. 18, p. 265.) We repeat a few paragraphs:

“The picture portrays the character of very many of the lawsuits carried on in our country. So long as the cow gives milk, it will be required for ‘expenses,’ and when this fails, the worthless carcass of the animal may perhaps be obtained by the litigant who has the most money, or the greatest physical endurance—each of them having in the mean time sacrificed the entire use

of the cow, and, besides, time and strength enough to have acquired half a dozen better animals.

“With most men, the first impulse, on having a slight difference with a neighbor, is, to ‘go to law about it.’ To submit the case quietly to the arbitration of disinterested persons, and yield to their decision, would not quite satisfy the dignity, nay, the belligerent propensity of the parties. How few men, comparatively, there are, who have lived forty years without having ‘been in court’ one or more times. And how few are the instances where even the victorious party has not lost more than has been gained—in time, worry of mind, expenses—to say nothing of the trouble entailed upon others who have been drawn into the conflict as witnesses, interested spectators, jurymen, etc. We have a vivid recollection of being called from pressing business to go fifteen miles to attend ‘county court,’ and of waiting four whole days to give evidence as a witness, in a case of which we personally knew nothing; and to cap the climax, the case was ‘adjourned over’ three months, when two days more were consumed in waiting. Our protestations that we knew nothing of importance, and that all we did know was hearsay, amounted to nothing with those in eager fray. The idea seemed to be that that side would be the strongest which could bring the most persons on the stand as witnesses, and so with more than twenty others we danced attendance. The whole amount at issue was less than our individual loss of time in one of the days spent at court. We received in return one shilling (12½ cents!) ‘in advance.’

“There is no doubt that most persons who would first sit down and count the cost of a suit at law, would be deterred from litigation, but for a feeling of false dignity. ‘I would expend the last cent before I would allow him to trample on my rights,’ is the common expression.

“But the pecuniary loss, serious as it often may be, is not the worst feature in the business. The hatred engendered, and bad passions nourished, re-act sadly upon the parties engaged. Said one who had finally obtained his suit,

involving a large amount, and one which he could ill afford to lose: ‘Had I foreseen the anxiety and vexation I have suffered from this business, I would have given a receipt in full for the amount, rather than have commenced.’ Many others will bear the same testimony. There are cases where it is positive duty to invoke the aid of law to secure or preserve rights, but reason, not passion, should preside when such interests are involved.—If any of our readers are tempted to indulge in ‘law,’ let them first give this picture a careful study, and then inquire if it will not be better to lose the milk at once, than to hold the cow with might and main, for an indefinite period, and in the end find all the labor lost.”

We are happy to say that we have but slight obligations, good or bad, to cancel with our legal friends. We have got along more than forty years without being actually called into court as a defendant or plaintiff, and hope to be equally fortunate the rest of our days. A libel suit, claiming \$10,000 damages against us, for an article cautioning our readers against land speculators, was commenced some three years since, but the parties failed to intimidate us into silence, though the complaint is still on file in some court. Our good legal friend, Wm. E. Robinson, Esq., put in a rejoinder which (thanks to his legal skill, and in this case legal brevity,) seems to have set the matter at rest.

But we will now give room to our able and worthy friend to put in his rejoinder to our pictures. Adhering to our rule not to contest ‘a case’ if it to be avoided, we make no response, but submit the whole matter to the jury of readers.

LAW, LAWYERS, AND LAWSUITS.

To the Editor of the American Agriculturist:

I have taken and read your paper for half a dozen years or more, and prize it highly. It has done much to change my homestead from a small city lot to a twenty acre farm in the suburbs of New-Haven. You have contributed not a little to my stock of horticultural, agricultural and pomological knowledge. Warmed by your enthusiasm I

have had, at different times and with various degrees of intensity, the pear fever, the berry fever, the poultry fever, and the hog fever—to say nothing of other distempers. From some of them I have not yet entirely recovered. I have reproached myself at times for not giving you something of my experience, for he who always receives and never reciprocates, is liable to be suspected of selfishness. But pressure of other duties has thus far prevented.

I belong to the best abused and the least defended profession in the world—the legal—having been a member of it for upwards of sixteen years, during which time I have had my full share of business, and all the professional success to which I was entitled. I mention it not egotistically, but only to enable you to see that I ought not to be ignorant of the subject about which I purpose to write.

A well digested system of just and equitable laws, and courts of justice to properly enforce and administer them, are absolutely indispensable for the security of life, liberty, and property. No civilized community can exist without them. Destroy them in this country to-day, and we will relapse into barbarism with a fatal rapidity unequalled by our wonderful progress thus far in all that constitutes national greatness. The confidence and security with which we lie down and sleep at night, in both city and country, is owing to the fact that the protecting shield of law is above and around us, and that we have courts to redress our wrongs. I will not enlarge upon this—its truth will be admitted by every one who will pause to think and reflect.—This being the case then, every one engaged in the work of ridiculing the tribunals, and their officers, which are constituted for the purpose of administering justice between man and man, is prosecuting a very bad business. His blows are aimed at the pillars of the State. He stabs at the nation's life.

In your December No. you illustrate your idea of lawsuits by a picture which is a fair caricature of some lawsuits, and of some lawyers and their clients. [Exactly what we designed it to be.—Ed.] It may in some cases do good—in many its tendency will be bad, if it prevents your readers from obtaining that justice to which they are entitled, and which they can not have, except through the agency of the courts. There is much litigation that might and should be avoided. It is equally true that there is much that should be encouraged. Sweeping, indiscriminate censure of lawsuits and lawyers is an easy matter. Any one can do it. It is much easier than just and fair discriminations. Such reformers need to be themselves reformed. They trim dead and diseased branches by cutting down the tree at the root. Your picture is of this character. No line or word gives to your many readers the fact that your illustration is a truth only as it describes exceptional cases, and that it is a monstrous falsehood so far as it conveys the idea that our courts and lawyers are engaged not in the god-like employment of administering justice between man and man, but in extorting money unjustly from credulous clients.

The picture you say has already caused some clients to settle their cases by compromises. If so, it by no means follows that they were wisely settled. Yet you conclude such was the case without knowing apparently the facts.* An insurance company refused to pay a widow \$2000 upon a policy which she held upon her late husband's life. I helped to recover for her a verdict of over \$2400 for debt, interest, and costs. She had two lawyers, and the case was taken to the court of errors by the company, and there abandoned, leaving the verdict of the jury in force. After my associate and myself had received all the "milk" we wanted, I had the pleasure of paying to the happy widow over \$2000. Now, while the case was pending, had she seen your

*Here is one of the cases. Two neighbors in this State had commenced a suit about a cow which promised to be a long one. They happened at the Post Office in a country store, as the *Agriculturist* arrived, to which they were both subscribers. Each opened his paper and saw the engraving. They laughed over it, approached each other in good humor, and settled their difficulty on the spot by mutual concession and agreement. They sent us a report, and we shall not tell how large a fee was presented to us in acknowledgment of legal services rendered.—Ed.]

illustration of the beauties of litigation, and compromised her claim for \$1000 by reason of it, you would have had another opportunity of congratulating your readers upon the happy influence your picture was exerting in diminishing and settling suits. But your picture would have cost the poor widow \$1000 in clean cash! I would recommend this case to your "artist." I could fill many numbers of your paper with other instances that have come under my observation, illustrating the same great truth, but it is unnecessary.

To rush into litigation to redress every little real or imagined wrong would be foolish, and there is in my judgment no class of men in the community who do so much to discourage it as the lawyers. I have had abundant opportunities of knowing this is true of the attorneys of this State as a body, and I believe it true of every other State. The most unselfish advice to settle and to quietly submit to little wrongs, is given constantly by the men who are so liberally maligned. [Such men we admire and honor—if there were not many exceptions, there would have been no occasion for our picture.—Ed.] A bad man loses his ease and he abuses the lawyers. A rogue is convicted of crime, and he curses the courts. A man wishes to be a villain and is afraid of justice—he thinks society would be improved if the law books were all consumed. A witness, bribed or biased, has his falsehoods exposed on the cross-examination, and he hides or tries to hide his dishonor by a prodigal abuse of the legal fraternity. A political editor having large self-esteem, a longing for office, and a narrow-minded jealousy, delights to ridicule and stab the legal profession, some of whose members he imagines are a little in his way. And sometimes a clergyman, who has failed as a lawyer, prefers to place his change of employment upon the ground that he is too good a man for so bad a business. And now and then the editor of an agricultural paper pauses in his enthusiastic admiration of fat pork and poultry, large cows, cabbages and colts, to eulogize libels upon one of the most laborious and useful professions. [Is the holding up to ridicule the practices of those foolish men whom good lawyers themselves try to keep out of the law, any "libel" upon the profession?—Ed.]

In the meantime the lawyers as a body smile at the narrow-minded folly of their assailants, and answer by a dignified silence. I stand almost, if not entirely, alone in attempting a reply. I do it in part to pay a debt, for I feel that I owe you an article or two. Another time I will select a subject more appropriate to your columns. FAIR PLAY.

New-Haven, Conn., Dec. 1, 1862.

Treatment of Wounds in Animals.

A correspondent inquires for directions as to the best treatment of flesh wounds in animals, what salve or liniment should be used, etc. It is a mistaken notion that any plaster, salve, liniment, or other nostrum, will heal a wound. The divided parts must grow together by the action of vital power in the flesh itself. The most we can do in the matter is, to place the separated portions under the most favorable position for uniting, and then let nature work. Of course the flow of blood must first be stopped. Unless some large blood vessel has been wounded, bleeding will usually soon cease. If however it continues long, and especially if the blood be of a bright red color, and comes out by jets or spurts, showing that an artery is divided, prompt measures are necessary, usually requiring some surgical skill. It is sometimes needful to hold open the edges of the wound, find the ends of the blood vessel, and tie them with strong white silk, leaving the silk long enough to hang out of the wound. In less severe cases, the application of cold water, or of alum water, or pressure, will aid in stopping hemorrhage.

In a simple cut, it is not necessary to cleanse

the wound from blood. Its coagulation will aid in the healing process, if the parts can be brought together and kept in contact. Foreign substances, as dirt, splinters, etc., must be removed before a cure can be looked for.

When bleeding has mostly ceased, bring the parts in close contact, and secure them by narrow strips of adhesive plaster. This article, which can be procured at any druggist's, should always be at hand. If, however, the laceration be extensive, it will be necessary to sew the parts together. Some means should be adopted to prevent displacement of the parts, after healing commences. To relieve the itching and irritation, the animal will endeavor to scratch or rub the wound, and thus often make it worse than at first. Bandages are useful, where they can be applied. They should not be too thick, for fear of heating and consequent inflammation. The animal should be kept entirely quiet, and the diet be made rather low. If much inflammation appears in spite of these precautions, an occasional moderate dose of Glauber's salts, together with the application of cold water to the wound, will check it. These general directions will answer for wounds not severe enough to require a veterinary surgeon. *

Imprisoned Animals.

Animals need shelter, but imprisonment is neither necessary nor beneficial. The horse and cattle stalls in too many instances supply only one requisite, viz.: warmth. Animals are frequently penned up from week to week, in narrow quarters, reeking with filth which fills the air with noxious effluvia, where little or no light can enter, as though they were undergoing punishment. Now even the best accommodations that can be provided, are in a measure unnatural. Our domestic animals at the North are natives of warmer climates, where they are accustomed to roam at will during the entire year. Every important change from this, their natural condition, will more or less interfere with their best development. If abundant and wholesome food, pure air, and plenty of light be supplied, the benefits of shelter will more than counterbalance the loss of freedom.

Confinement of animals should not be too strict. Some amount of exercise is indispensable. The horse that is kept standing on the stable floor for weeks, will be troubled with swollen limbs, loss of appetite; will be likely to acquire the habit of cribbing; and when finally used, will over-exert himself, and then quite likely be laid up for a time with stiffened muscles. Cattle become restless and feverish from long confinement, and will not lay on fat, or give a full flow of milk, without a moderate amount of exercise daily. A good plan is to turn them loose in a sheltered yard after the first feeding, while the stables are being cleaned. Animals as well as men enjoy a change of place, and with these their health and comfort are intimately connected.

Cure for Foot Rot in Sheep.

A. A. Goff, Farmington, Ohio, contributes to the *American Agriculturist* the following preparation for curing foot rot in sheep, which he says has been very effective in his neighborhood: "Mix 3 oz. each of blue vitriol (or sulphate of copper), white vitriol (or sulphate of zinc), verdigris (or acetate of copper), and gunpowder, with ½ pint each of alcohol, spirits turpentine, and strong

vinegar. Cork up tightly a few days before using. It is easily applied from a vial having a quill inserted through the cork. By dropping this mixture into the affected parts three times, once in ten days, a cure will be effected."

One of the ingredients of the above mixture, viz.: sulphate of copper, in strong solution, has long been used by successful sheep owners, as a specific for the cure of foot rot. Randall, in his work on Sheep, details numerous cases cured by himself with this treatment. Whether the addition of the other articles is beneficial, we are in doubt, and should recommend to try it only after the sulphate of copper had failed.

In applying either remedy it is essential to pare away the hoof from the affected parts to get at the diseased tissues, and thoroughly saturate them with the liquid. The solution of blue vitriol should be used as hot as can be borne by the hand. Extended directions for the treatment of this disease were published in the *Agriculturist*, Vol. 20, page 141 (May 1861).

For the American Agriculturist.

Raising and Training Colts.

The earlier in life the education of any animal commences, the easier will be its training and the more certainly will its habits be fixed. Horses learn most of their vices before they are three years old, and in a large number of instances the work of "breaking" them does not commence before the second or third year.

Begin when the colt is *one month* old. Put on him a leather or web halter, without the hitching strap. Let it remain there and you will have control over him when you wish to handle him. Have a leather hitching strap with a buckle or clasp on one end, to fasten into the halter ring when you wish to lead or tie the colt. Never tie a rope or a rope halter around the neck. Allow the colt to nibble at his dam's feed while she is eating. After he has become accustomed to the halter and to being led about and handled, you can tie him alongside of his dam at feeding time, watching him the first time to prevent his pulling back, and afterward if he shows a disposition to pull. Never speak harshly to, or abuse either dam or colt. You can do more by kind, firm treatment than by abuse of any kind.

Wean the colt at his seventh month, keeping him out of sight and hearing of his dam for several weeks. Give him a pint of good oats with plenty of sweet hay morning and evening, also fresh pure water. As he grows larger, increase his feed, always giving the best. Remember the colt is now forming the bones and muscles upon which his future usefulness depends, and he can not form strong, solid ones without good strong feed and good shelter. Give a feed of chopped stuff and cut straw several times during the week, to keep his system cool, and to prevent the "lampas." If he should take them, put him on soft feed, occasionally giving him a bran mash, until the lampas disappear. Keep the colt under shelter during the Winter nights, and on stormy days and nights at any season of the year. A loose box or stable in which he can be placed without tying, is best; next, a stall six feet wide in a stable well lighted, drained and ventilated. Have a ring and staple driven into the manger bar, to tie to. The best plan for tying, is to pass the halter strap through the ring and tie it to a small weight, heavy enough to keep the strap always drawn tight. Have the strap long enough for the colt to lie down with his head flat on the floor; the weight will always keep the strap stretched so that he can not get

his feet over it. Keep the stall well littered at night and perfectly clean during the day. Do not put the litter under the manger when cleaning out the stall in the morning, but throw it under a shed outside of the stable, to dry before using at night. The ammonia arising from the urine decomposing in the litter is very injurious to both eyes and lungs. Frequently sprinkle some good deodorizer on the floor to absorb and destroy all noxious gases. Accustom your colt to harness, and to saddle and bridle, by putting them on frequently, and letting them remain on for a half hour. Train the colt without blinders on the bridle. Never draw the check rein tight. For fast driving, it is better to dispense with it entirely. I would not advise an inexperienced person to use the biting bridle, but if used, let the reins be loose. If possible, it is best to let the colt run until three and a half years old, and if very valuable, until five years of age before putting to regular service. You can teach the colt the use of the lines before he is fit for service, by putting on a surcingle with rings fastened to it, two thirds down each side of the colt. Put the reins through the rings and buckle to the bridle. Walk behind the colt and teach him the use of the lines. The rings on the surcingle will prevent the reins from slipping up over his back if he should try to turn; by holding your hands low, it is impossible for him to turn. If he backs, touch him lightly with a stiff whip. By the above training the colt at three years of age will be ready to put to light work, though I would advise waiting a few months longer. The subsequent training will depend on what use the horse is intended for.

Alleghany Co., Pa.

R. S. W.

Colvin's American Milking Machine.

Our recent files of English papers have much to say of this apparatus. The *Agricultural Gazette* sent out a special reporter to witness recent trials in the dairying districts of England, and a single number of that journal has some ten columns upon the performance of the machine. The inventor appears to have met much better pecuniary success abroad than at home.

Two or three years since, the machine was brought to our office with a request for a favorable notice in the *Agriculturist*. It did not seem to us to meet the high claims made by the inventor, and before deciding as to its merits, we asked permission to try it upon our own place. This was not acceded to, and the exhibitor left, remarking that it was all right, and that it would be sure to go with the people whether we endorsed it or not.

At the recent International Exhibition in London, one of the proprietors was on hand with the apparatus, where its novelty immediately attracted great attention, and we were informed that large sales were made. We tried to witness it in operation, but were unable to be present at the exhibition at the right hour. After a very careful examination of the apparatus itself, our previous impressions of its value were not changed. The machine is arranged with India-rubber sockets to receive the cow's teats, and the milk is drawn out by an ingeniously constructed pump attached to the pail. If such an apparatus can do the work well, it is a most desirable invention, but we feel strong doubts as to its practical success. The operation of hand-milking most nearly resembles the sucking of the calf, and is therefore likely to be most effective. In the *Agricultural Gazette* reports, it is ad-

mitted that the cows were not all milked clean, that some of them proved refractory, and others held up their milk. These objections were met with the excuse that November is not the time to begin with the machine, after the cows have been hand-milked all Summer; that in Spring they will yield more readily. If this excuse be admitted, the sales will probably go on in England during the Winter, and an opportunity will be given for the American public to learn the final results. We are quite willing that English farmers shall be at the expense of the doubtful experiments, and that the manufacturers there shall make the first investments in the patent. We are quite ready to say a good word for the machine, if the patentees can show by fair practical experiments that cows can be milked clean with it, at saving of labor.

Feeding Turkeys in Winter.

Where corn is cheap, and the bins are full, nothing better is needed. But unfortunately many who like roast turkey, have their bins nearly empty, where corn is nearly a dollar a bushel. These birds will eat longer of corn than of any other food. They seem never to get enough of it. But they are by no means dainty in their diet, and will eat any thing coming from the kitchen that a pig will devour, if it be properly prepared. They will work up the refuse material from the farm and garden, about as well as pigs.—Boiled potatoes, fed warm, are highly relished by them. In this way potatoes, that are too small for marketing and for seed, may be turned into roast turkey on very short notice. If the parings and slops from the kitchen are boiled and mashed with them, it is all the better. But they need a variety of food, green as well as cooked, in order to thrive most rapidly. They are very fond of cabbage, and will feed upon the refuse plants that have not headed, until the stumps are picked bare. If these are not on hand, raw turnips chopped up fine will be readily eaten. They need also some animal food to promote growth in Winter. Beef scraps from the tallow chandlers or butchers are as highly relished as by hens. Nothing in the way of animal food comes amiss. It is of more importance that the food should be abundant and various, than that it should be select.

In fattening, some shut them up in a room partially darkened, and feed with scalded meal and pounded charcoal; but we object to the confinement of the turkeys. It is almost impossible to keep the food clean and to prevent waste, and they are quite as restless as when they have their liberty. With regular full feeding at night and morning, they will not wander far from the yard, and will take no more exercise than will be for their health, and the best flavor of the flesh. By this process of feeding, a late brood of turkeys may be brought up and fattened in Winter, without any serious encroachment upon the corn bin. With turkey at fourteen cents a pound, it is a very convenient article of barter, at the village store, and not hard to dispose of in the home market. The relief from salt junk by the winter feeding of turkeys is immense.

QUESTIONS FOR QUACK DOCTORS.—Will eating roast duck give a man a fowl stomach? And, if so, will the flesh of neat cattle be a good cleansing agent? Does eating green corn produce huskiness of voice? What kind of hose should be used for corns, particularly where there are several *achers* under cultivation?

MALLORY & SANFORD'S IMPROVED FLAX BRAKE.

Prospects for Flax Culture—An Improved Brake.

The long and prosperous reign of cotton as king of textile materials, has in good measure thrown into obscurity the plant that from earliest history gave royal robes of fine linen to monarchs and comfortable apparel to their subjects. In the memory of many now living, no farmer's stock of implements was complete without the flax brake and the hackle at the barn, and the foot spinning-wheel by the fire-side, with which, and the loom, were wrought from the annual crop, clothing for the present use, and for the daughters' dowry. It is consoling to know that if the accustomed supply of cotton be cut off by the desolating storm of war, we have yet resources which have in former times proved adequate to furnish the necessities, if not all the luxuries, of late years supplied by the southern staple. Numerous costly experiments have been long in progress to discover, if possible, some mode of treating flax to render it capable of taking the place of cotton, and though the end is not yet fully reached, advancement has been made, and ultimate success is not hopeless. A large establishment in New-England formerly used for the manufacture of cotton goods, we believe, has recently been purchased by a company for the purpose of working flax on cotton machinery, under new patents, for the production of what is called flax-cotton.

But even if flax can not be manipulated so as to come into competition with cotton, and supposing the supply of the latter to be fully restored, there is yet a good prospect that flax-growing will prove remunerative. The supply of the staple for the manufacture of lineus and other fabrics has been growing more and more scanty for some time past. A year or two since an agent was sent to this country from Great Britain to inquire concerning the amount produced here, and to take measures if possible to increase the breadth of land devoted to this crop. In addition to the call for flax for manufacturing purposes, the seed is in constant request,

and, by itself alone, is considered in many sections as good a paying crop as wheat or corn.

It is evident that to make flax-growing pay well, at least in ordinary times, it is necessary to employ improved machinery in preparing the fiber for market. Flax-dressing by hand is too slow to be profitable. Mills in various parts of the country are ready to perform this work, but they can serve for only a limited area; flax in the straw is too bulky to allow of distant transportation. On account of this difficulty the fiber has been wholly neglected in large districts where the plant is cultivated, and only the seed has been saved, for the manufacture of oil. We have recently examined a newly invented flax-brake intended to meet this want, which if successful will do much to stimulate flax culture. The machine is shown in the above engraving. It consists of a series of fluted iron rollers, seen at the top, between which the flax is drawn from the feeding board. A peculiar vibratory motion is given to the rollers by means of ingeniously arranged gearing seen near the base of the machine, which causes the flax-straw to pass repeatedly back and forth between the rollers, and it comes out with the "boon" or woody part so thoroughly broken that a very large part of it (64 per cent, it is claimed) can be readily shaken out of the fiber without any further dressing. Machines for a similar purpose are already in operation at flax mills, but they require trained workmen to tend them, greater power to work them, they leave a large part of the "shoove" or broken straw mixed with the fiber, and their operation is not without danger to the workmen. Numerous instances of the loss of an arm have occurred to inexperienced operators. The Mallory & Sanford brake can be run by an ordinary horse-power, and any laborer can use it without danger. Another advantage claimed for the new brake is a great saving of fiber. In experiments made in the flax mill at Union Village, Rensselaer Co., N. Y., 500 lbs. of flax straw dressed on a brake of the old pattern, yielded 92½ lbs. dressed flax, 43 lbs. coarse tow,

and 9 lbs. fine tow. A like quantity of the same quality under the new brake gave 110½ lbs. dressed flax, 16 coarse tow, and 3 lbs. fine tow—a gain in good fiber of over 3½ per cent. The greater weight of tow in the first lot above the 10 lbs. saved in the "line" or dressed flax, was owing to the larger quantity of "shoove" or broken straw remaining among it, rendering it of less value than the tow from the new brake. The capacity of the above machine is said to be from twenty to twenty five hundred lbs. of flax-straw per day of ten hours. If the above claims of the inventors are reliable, and they appear to be well substantiated, the machine will greatly aid in making flax culture more profitable. Further information concerning this apparatus can be obtained from Messrs. Mallory & Sanford, corner of Center and White streets, in this city, where the brake may be seen in operation.

We consider the subject of flax culture of such importance that we are preparing to give during this year the fullest possible information on all the practical points involved. We are already in communication with those who have had much experience in the business, and shall lay the result of our investigations before our readers in time for putting in the next crop. We will also esteem it a favor if those of our subscribers who are familiar with flax culture will contribute their knowledge on the subject for the general benefit, giving particulars as to best soil, proper preparation of ground, time and manner of sowing, quantity of seed per acre, after-culture and treatment; in short all the items that the inexperienced desire to know.

Agricultural Inventions in 1861.

In the last number of the *American Agriculturist* page 326, we gave a synopsis from the latest official list of some of the patents issued in the year 1861. The topic is worth referring to again, for there is perhaps no better indication of the progress making in agricultural science and practice. The progress already made is very great. It is probably safe to estimate that the inventions of 1861, as compared with the implements in common use only twenty years ago, will effect a saving of the labor of more men than are enrolled in our great armies, even if these men were all taken from the farm. The demand which calls forth these inventions, shows that farmers are not satisfied with the old methods, but are looking for something better. As long as people were content to mow an acre a day with the hand scythe, no machine was thought of, capable of doing the same work in a fifth part of the time, and with brute force instead of human muscles. The same may be said of the horse-rake, which puts the larger part of the afternoon work of the hay field upon the horse. So of all the other inventions that lighten the labors of the husbandman and increase his profits; they have their origin in the conscious imperfection of the old implements. The list of inventions furnishes a good mirror of the thoughts of the farming population, and shows whither the current is tending.

We find in the list for 1861, twenty-five inventions pertaining to bee-hives, showing that a new impulse has been given to this branch of rural economy. The interest in hoed crops is represented by fifty-three patents for cultivators. When it is recollected that in each one of these patents are represented a number of unsuccessful applicants, it will be seen that a great amount of study has been bestowed upon a field of in-

quiry already pretty thoroughly explored. With the steel tooth cultivators of former inventors, or with Share's horse-hoe, there was no difficulty in doing nine-tenths of the tillage of the corn crop in the most satisfactory manner. There are nine patents for seed drills, showing that there is dissatisfaction with the common mode of sowing grain broadcast. There are ninety-seven patents for harvesters, mowing machines, reapers, and their various appendages. The inventive skill of the country seems to be specially directed to the most economical method of gathering our hay and grain harvests. The problem is solved, for we have now machines that put all the exhausting labor of the hay and grain field upon the muscles of the horse, and greatly lessen the drudgery of the farm, almost turning it into agreeable pastime. The great West and the boundless prairies speak in these inventions.

One might think on inspecting any of four large agricultural warehouses, a (single one of which enumerates more than a hundred kinds,) that plows were nearly perfected. Our inventors are not of that mind, for we find in the list, sixty patents for plows and their appendages. Something must be the matter with the old methods of dropping seed, for we find thirty-seven new seed planters, most of them for corn. The days which shall see a boy dropping corn from a basket with a man covering with a hoe, are nearly numbered. The writer tried one of these horse corn planters last Spring. A man and boy easily planted ten acres a day with it, which is some improvement upon one acre a day. The corn came up as well and made as good a crop as if it had been planted by hand.

Beside these, there are a great variety of seeding machines, grain separators, thrashing machines, machines for sowing fertilizers, spading machines, straw-cutters, horse-rakes, feed cutters, corn shellers, and over twenty new churns, showing that the war has very little affected the inventive genius of our people, or impaired our capacity to feed ourselves and the world.

Evans' Rotary Digger.

The report given below indicates that this implement is at least an approach to what has long been desired, as an improvement upon the plow: "The undersigned committee, appointed to examine 'Evans' Rotary Digger,' exhibited by Mr. H. C. Hepburn, at the State Fair at Rochester, respectfully report, that the machine was submitted to them in operation on a field near the Fair grounds. The soil was a loam of medium texture between the sandy and clayey, and had been cropped the past season with beans. The machine was drawn by a pair of farm horses rather under the average strength, making at each passage over the field a cutting *twenty inches wide and eight or nine inches deep*. It moves on three wheels, and weighs in its present condition, as stated to the committee, 1,200 pounds. The operation of the revolving teeth or diggers, upon the soil, is similar to forking. One passage over such soil as that on which it was tested before the committee, appeared to loosen and pulverize it to the full depth of the teeth or diggers, but when twice passed over the same cutting, the weeds and grass had nearly all disappeared, and the soil was made so loose that persons walking over it sank as they would in a mass of newly fallen snow. The committee take pleasure in saying, that, on the whole, they have been well pleased with what they have seen of the practical working of 'Evans' Rotary Digger,' and concur in the opin-

ion that it is in a fair way of being made a machine of great value for the pulverization of the soil. All of which is respectfully submitted. LEWIS F. ALLEN, of Erie; SAMUEL L. FULLER, of Livingston; P. BARRY, of Monroe, *Committee*."

Inoculating Meadows.

In a foreign exchange, we find mention made of Wedlake's "turf-separating machine." This is nothing very new. It is a machine with which to lay down parks, meadows and lawns by inoculation. It resembles somewhat a common straw-cutter, and is used as follows: The land to be treated must be plowed, harrowed, cleared of all lumps, weeds and large stones, and then rolled smooth. Go now with a paring-plow to some common or roadside, where the turf is of good quality, and having sliced off a suitable quantity, stack it up in small, loose heaps, where it will become partially dry, and easily broken into fragments. This prepares it for the machine, into which it is put, and torn and separated into small fibres, or numberless distinct plants with roots. Before the plants become much withered, take them by the basket full and walk over the field, sowing them broad-cast, like grain. (It should be said, however, that this sowing should be preceded by a light scarifying of the surface with a harrow.) After the sowing, follow with a roller, which will compress the roots a little into the earth and give them a hold on the ground. This process in a good grass season insures a fine turf in a single year.

Turning out to the Right, or Left?

Long custom is not easily changed, and reasons "as thick as blackberries" are always to be found, for "doing as our fathers did." This has been fully verified by the mass of communications called out by the article in the *American Agriculturist*, (Oct. No., Vol. 21, page 302,) showing the desirableness of teamsters adopting the English practice, and turning to the left, when meeting. An anonymous writer, "E. O." presents the opposite view quite forcibly. His reasons for opposing the changes are: the difficulty of obtaining common consent; the existing laws to the contrary; the necessity of altering the construction of all one-horse sleighs, the thills of which are now placed in accordance with the present manner of turning out. He is however in favor of the driver changing his seat to the left, that he may better keep his vehicle from collision. He gives an additional reason for this in the fact that the step upon carriages is on the left side, and if a lady is first handed in, the driver must crowd past her to his place on the right—not easily done in these crinoline times. He has practised driving seated on the left for years, and likes it much better.

Perhaps our correspondent can use the whip well with his left hand, otherwise both he and his lady would occasionally find it awkward business for him to give a strong right-handed blow, while seated on the left. The necessary change in sleighs would cost less in the end than the damage resulting from collisions—particularly in crowded cities, and as for laws and customs, they should be helps and not hindrances to improvement. If the propriety of a change of custom be generally agreed upon, it will not take long to make all needed legislation, and to re-model the one-horse sleighs when used. After hearing both sides pretty fully, we adhere to our position on the question, and all things considered, it is better to "Turn out to the left."

Branched Bean Poles.

"Y." of Saratogo Springs, N. Y., communicates his experience to the *American Agriculturist* as follows: I have been for a number of years, a successful cultivator of Lima beans, and now give you my *modus operandi*. My poles, which are dwarf maple, hickory, etc., say nine or ten feet in height, are cut, leaving their tops on. These poles (which I put under cover in the Winter,) usually remain sound five or six years. Early in the Spring, I have my bean patch well worked, then have holes dug, say two feet by eighteen inches, then dump into each hole, about $\frac{1}{2}$ a bushel of fresh horse manure, cover with rich earth; then, with the aid of a crowbar, set the poles, and plant the seed in a circle around each—say half a dozen beans, with the eyes downward. These, after they get beyond the reach of grubs, I thin out, leaving three in a hill, and I have never failed in raising a good crop. True, I am compelled at times to cover them up nights, by placing newspapers around them, held down by stones or lumps of dirt, to protect them from frost, but I am well repaid for the trouble. I can raise from the same number of hills, *with brush on the poles*, more than double the quantity of beans that can be raised on the old-fashioned crowbar pole.

For the *American Agriculturist*.

Good Way to Make an Asparagus Bed.

With a two-horse plow turn a deep furrow each way, this will open a ditch two feet wide to the depth of the soil. Then run the plow in the bottom of the furrow and loosen the clay, or subsoil, as deep as possible, and throw this out with a shovel upon one side. Place in the ditch six inches of half rotten manure, cover it with a slight coat of the soil, then make a small mound of sand or fine earth (sand is best), every two feet, in the center of the ditch. Set the crown of the plant upon it, and cover with sand slightly; then shovel or plow the soil over the plants three inches deep, which will bring the surface level again. Next take the plow and one horse and run close to this row, throwing the soil from it, then turn the other way and throw the subsoil on the first planted row where it may remain. Clean out this second ditch with the shovel and proceed to plant the asparagus roots as before; and in the same manner extend the bed to any desired size.

The planting should be done in the Fall, and the clay that is thrown on the top will be pulverized by the frost and sufficiently enriched by a coat of four inches of manure, which should be spread over the bed as soon as the frost has decomposed the clay upon the bed. This I think the cheapest way of making a good bed, for it must be made *deep* to be durable. One-year-old plants are best. I have them now from seed obtained from the *American Agriculturist* last Spring, that have a circle of roots over a foot in length. By setting them upon a cone as described above, they are placed exactly in their natural position, with the ends inclined downward towards the manure and moisture; and the earth coming in closest contact with them. And, by the way, this is the proper plan for setting all kinds of plants, or trees, that have fibrous roots, between which the earth will not readily pass, the great object being to get the earth in closest contact with the roots. A good coat of manure and salt should be spread over the asparagus bed every Fall; and it will produce for an age.

Montgomery Co., Md.

For the American Agriculturist.

Shall we Teach Agriculture in Common Schools?

This question has been agitated, more particularly in New-England, for the last few years, and from the multiplicity of articles upon the subject in the papers from this quarter, we see is still up for discussion. Manuals have been prepared and those who publish school-books and understand the engineering necessary to get them introduced to the school, are the busy advocates of this branch of agricultural reform. To show precisely what is aimed at, we quote the words of one of these reformers as given in an agricultural address.

"Botany, or the study of plants, grains and vegetables, should be a prominent study in our common schools, commenced with the alphabet, and continued to graduation, so that every boy and girl 14 years of age, can not only tell the growth and food of every grain and grass and vegetable, but also what soil and season, and fertilizers are best for it. Chemistry also should be studied from the earliest period to the latest, as we now study arithmetic and geography. It is vastly more important for a person to know the prime gases than the prime numbers. Arithmetic, geography, and grammar, are studied to the neglect of other more important and attractive branches of knowledge. Teachers should be trained in our Normal schools not in Algebra and geometry only or chiefly, but in botany and chemistry, and meteorology."

If we understand this reformer aright, he would have all the natural sciences which have a bearing upon husbandry taught in the free schools, and have the children indoctrinated in these sciences, by the time they are fourteen. Botany is of no more use to a farmer than zoology, entomology, geology, and perhaps we should add ichthyology and conchology. If it is profitable for him to understand the science of plants, it must also be useful for him to know something of the insects that destroy them. Fish and shells make excellent manure, and so would come appropriately under the young farmer's studies. But these are only the auxiliary sciences to the great study of husbandry, a business that requires more varied knowledge than almost any other avocation.

The unreasonableness of the demand of these reformers is apparent, if we consider that children in the free schools have already more studies than they can master in the brief period of attendance. It is not profitable or hardly safe to send a child to the drill of the school room before he is seven years of age. Before this age, his best place is in the nursery and the open air, attending to *physical* growth. Surely, the seven years previous to fourteen are not too long a period to master the branches usually taught in the free schools. A farmer should know how to read and write well, or he might not be able to keep posted in the various branches of natural science, after he commenced business. He should be ready at figures, or his pecuniary affairs might suffer loss. The farmer sustains certain relations to society and is as liable as other men to be called to fill positions of trust and responsibility. It is therefore important that he should know how to use good English, whether he get the "prime gases" in due order or not.

The natural sciences are appropriately studied in our higher schools and colleges. Men and women of adult years and with all the advantages of laboratories, collections of specimens, accomplished lecturers, and months if not years of study, are only able to get the first principles of these sciences. So little progress is made in the ordinary college course of

study, that unless a young man has a peculiar taste for these studies and pursues them zealously in his vacations, and after graduation, they are never of much practical value to him. They make him more intelligent, and the discipline is valuable, but he does not so far master these sciences in his college course, as to make them of much use, or to make him a fit teacher of them. How then can it be expected that a child of fourteen is to get knowledge enough of these sciences to be of great advantage to him.

We have not the teachers of requisite knowledge to instruct children in these studies, even if it were desirable. Most graduates when called to teach any one of these branches as a specialty, feel the need of extra preparation and training to fit them for their work. Much less then could it be expected of our common school teachers, to instruct our children in sciences they have never studied. It would take years of special training to prepare them for it, and when they were fitted they could not afford to teach at the wages now given in the free schools. Higher qualifications in the teacher, of course imply the necessity of higher remuneration.

Then we have not the conveniences for teaching these sciences in our common school houses, and can not have them without a total change in our system of education. The teacher of chemistry needs his laboratory with some apparatus, lamps, retorts, blow pipes, jars, earthen, metals, etc. All the natural sciences need apparatus and specimens, to be studied with profit. We can not have these in the school house, for it is not built for the purpose. Any effort to introduce these studies would naturally divert the minds of the children from the branches commonly taught, which are necessary for all classes. It would result in a smattering of knowledge without thoroughness in any thing.

Then it would inevitably provoke the jealousy of other classes not engaged in farming. The shoemaker and the blacksmith would be afraid that the children of farmers would have more than their share of the teacher's attention, if the study were optional; and if it were compulsory, it would breed a rebellion, and oust the teacher or school committee. Every one who has had much experience in the management of these schools, can see that the thing would not work. It is a common school, and only for those studies which are the common want of all.

We want as a preparation for entrance to agricultural schools, pupils well drilled in the branches now taught in the common school, and the time now allotted to these studies is none too long. Farmers should stand upon a level with other classes in these studies, as well as have special knowledge of their own business. This will have to be learned in schools specially devoted to agriculture, and upon the farm. Though this will not be so well for manufacturers of school books, we have no doubt it will be better for farmers. A NEW-ENGLANDER.

REMARKS ON THE ABOVE.—It appears to us that in the above article the writer has taken rather too strong ground, though probably right in the main. The common branches, reading, writing, spelling, arithmetic, and geography, should certainly be the first studies, and be well mastered. But along with these, partly as a recreation perhaps, may well be introduced easy primary lessons in chemistry, in what is termed Natural Philosophy, in botany, physiology, and geology. The teacher is poorly fitted for his or her sphere of labor who can not give to a whole school at least some "talks" on these branches. If not prepared to do so, he should

omit some evening parties and "study up." Fifteen or twenty minutes time in the school room daily devoted to a short talk on these branches, will scarcely retard progress in other studies, and will afford a pleasant relief to both scholars and teachers. A little knowledge of the elements, of physiology or the care of the body, of the first principles of natural philosophy, of botany or the structure and growth of plants, of geology or the way soils are made up and arranged, will awaken interest and inquiry, cultivate a taste for these studies, and beget an important habit of observation—to say nothing of the practical utility to the future citizen, of even a little such knowledge. The trite saying, that "a little knowledge is a dangerous thing," is false as a rule. *The great mass of children will never get any idea of these useful and interesting sciences, if it be not got in the common school before the age of fourteen.* A few ideas inculcated there, will lead to useful reading, thought and investigation, afterward—to the less reading of trashy, exciting novels.—Not much apparatus is required. A few very simple experiments are enough to awaken interest, and explain the first principles. The best chemistry class we ever examined was one of boys and girls in a common school, from 12 to 16 years old. The teacher expended on simple materials, \$8, contributed by a few individuals. The first electrical machine we ever saw (and a very effective one it was), we made while yet in the public school, with materials found wholly on the farm, except a single glass jar for the main cylinder. For a guide we had an old Comstock's philosophy sent as a present by an Eastern friend.—O. J.

Profit of Sheltering Manure.

It is now pretty well settled by the experiments of intelligent agriculturists, that manure protected from the weather is much better than that which has lain for six months or more in the open yard. Every farmer who has cleaned out under his stable floor where there was no cellar, or has used the manure made on the floor of the sheep barn or shed, has had occasion to suspect as much. Crops fertilized with such protected manure started with great vigor, showing a dark green color, and pushed on rapidly to maturity. There must be something in such manure that the unsheltered article loses.

An English experiment shows that manure which was kept covered by nine inches of earth, produced several bushels more of grain per acre than the same amount of manure applied to the same extent of land, but which had lain exposed to the weather during the Winter. Another experiment shows a difference of about four tons or nearly one hundred bushels, between the produce of two acres in potatoes, the one of which had 20 loads of covered, and the other 20 loads of uncovered manure.

A gain of fifty bushels of potatoes to the acre, just from the difference in the quality of the manure, is worth looking after. It will be seen that this is nearly all clear profit. There is no more expense for seed, for handling manure, or for tillage. The only additional item would be the increased labor of harvesting. The conviction that the housing of manure is good economy is pretty general, and yet not a fourth part of our farmers pay any attention to it. The open yard without a barn cellar, and even without sheds, is still a very common spectacle.

The best substitute for lack of cellar is a covering of earth, or muck, for the manure, as fast

as it is collected. If the open yard were kept well supplied with muck, and the manure were to be plowed under every month but without draining off, it would not waste much. Where straw is plenty, as in the wheat growing districts, it makes a very good covering for manure. This is the practice of some of the best managers. But it requires a much larger quantity of straw than most of our farmers have for litter. The straw is thrown out frequently, and the yard is kept nearly dry for the cattle to lie on. Muck usually costs nothing except the drawing and hauling, and rightly managed it makes a good protection for manure. It should be scattered frequently over the yards and under the sheds, and the heaps kept well covered.

A CAUTION.—A Canadian subscriber to the *Agriculturist* complains that he has followed our advice, and that his manure dried up, heated, and was nearly spoiled—in other words it “fire-fanged.” This reminds us to repeat, that while no liquids should be allowed to run from the manure heap, it *should always be kept moist*. The heap should be frequently examined, and if found drying out, water should be added. The best plan is to pile the manure in a tight vault or excavation that will hold the liquids. If not under a roof, a cover of loose boards will answer, as a little rain falling through will do no harm. Then, as often as needed, pump up or dip up with a bucket, the liquid from below and spread it over the heap. This liquid manure will hasten the decomposition of the straw and other coarse materials, and all the heap will be equally rich.

The “Dakota Potato,” or Ground Nut.— (*Apios Tuberosa*.)

To the Editor of the *American Agriculturist*.

This plant, Eaton, in his *Botany*, more than thirty years ago, said: “ought to be generally cultivated.” And it appears by the December *Agriculturist*, others have taken the hint, as well as the undersigned, in making the trial. Six or eight years ago I procured some of the tubers from the State of Maine, and some also from this immediate vicinity, (Middletown, Ct.,) and planted them in my garden, but I am sorry to say my success has been poor indeed. So far as my own experiments can be relied on, they do not appear to improve by cultivation, in the least, nor even to grow as well as they do in the wild state. I have not yet been able in my garden to produce tubers as large as are often found in their native situation. I purpose to continue the experiment a few years longer, however. J. J.

Sweet Potatoes in Ireland.

“Hibernia” inquires if sweet potatoes will flourish on his farm near Belfast, in the North of Ireland. We judge not. If we remember rightly, the soil thereabouts is not sufficiently sandy and warm. A light, moderately sandy, warm soil suits this crop best, though we have grown them well on a pretty stiff loam, by high hilling. Probably, however, the soil would answer, if there were sufficient sun light. In the sea-girt islands of Great Britain the air is almost always moist, and bright skies, warm clear days, such as the sweet potato flourishes best under, are not the general rule there. Perhaps the longer absence of frost, owing to the proximity of the never-freezing ocean, may in part make up for the less sunlight. It would be well to try the experiment. The common *Nansmond* variety can be purchased in our mar-

kets. These, packed in dry sand in a box, and kept from freezing, can be carried over at any time during Winter. Put them into boxes of earth in a green-house or hot-bed in March, and abundant sprouts will start out. When 6 to 10 inches high, break them off from the tuber, keeping as many fine roots on the stems as possible, and transplant out into high hills or ridges, when the soil is warm and danger of frost past. The ground should be well supplied previously with thoroughly rotted manure. For directions, see *American Agriculturist* for April, 1862, (vol. 21, page 109), and an article to be published a month or two hence.

For the *American Agriculturist*.

An Iowa Corn-Marker.

Iowa is well adapted to the cultivation of corn, yet many are so careless that weeds often get the mastery, hence they get a poor remuneration for their hard toil. One great reason is, that after fitting the land for seeding, they spend several days in “furrowing out each way,” with a shovel plow, jogging along in a zigzag manner, so crooked that a squirrel can hardly find the rows after it comes up. This requires much labor, and is of no benefit except in making easy planting. The corn is placed too deep to feel the warmth of the sun when it needs it the most, and the farmer has to wait too long for the corn to get large enough to keep from covering it up the first time through with a plow or cultivator. Corn needs light, air, and warmth to vegetate and grow rapidly; to obtain these abundantly I can not think a deep furrow favorable. My way is to plow deep and harrow lightly to level the surface, then make a marker after this fashion.—Take two hardwood poles, or scantling, fourteen feet long, lay them parallel, and pin to them at right angles four blocks two feet long and two inches thick, at a distance of three and a-half feet apart. Slant off the front ends of these blocks, making them like sled runners. Turn the apparatus over, fasten a tongue to the middle of front pole, and the marker is complete. Hitch on the horses, take your place on the center of the marker and drive on until the field is marked in one direction; then cross-mark in the same way. Stakes should be set at each end of the lot to guide by, instead of merely trying to run parallel with the last mark. Fifteen acres can thus be marked each way in a day.

C. J. RHODES.

Tama Co., Iowa.

How Corn is Made in Egypt (Ill.).

[The following plain, straight-forward account of the common mode of cultivating corn in Southern Illinois, from Wm. O. Marvin, of Randolph Co., will give a partial picture of farm life there, and perhaps afford a hint or two. The plan described is doubtless susceptible of improvement. A brief description of the methods pursued in different sections, not only with corn but other crops, would be useful to others.]

“We prefer for Indian corn, wheat stubble unbroken until plowed for planting in the Spring: *First*, the cut worms trouble it very little; *second*, should the season be dry it bears the drouth much better than our other lands; and *third*, such land is most easily kept clean. The plowing should be at least eight inches deep, and all the growth of weeds and grass be turned to the bottom. After it is well broken, we lay it off one way in rows four feet apart, and 5 to 6 inches deep, with a one horse plow. It is

then crossed with the marker, making six rows to the round. Our children usually drop the seed. Some cover it by throwing on one, and some two furrows with the small plow, and just before it is up, harrow it down level. Others cover with the harrow alone. Others cover by dragging a suitable flag stone across the rows, which is by no means a bad way, as we have no stones in our fields to interfere with culture. But we think the hoe is the best implement of all to cover with, and this is the only use we make of the hoe in producing the crop.

When the corn is up so that it can be worked, we remove the front tooth (or share) from a cultivator, and with a span of horses run it astride the rows, first one way, and then across. This works the soil between the rows, and close up to the hills, in both directions, leaving it clean and in a condition little inferior to the best hoeing, and the hills are made around the corn. [This lets in the sun to warm the roots and promote their growth.] The labor is not half that of hoeing. The after culture depends upon circumstances. If rains harden the surface, the plow may be required. After plowing, a one-horse cultivator is run between the rows to level off the surface, as we prefer flat culture to high ridging around the hills. By the above process we get, in common years, from 40 to 60 bushels per acre, according to the quality and condition of the soil.”

Change the Locality of Seed—An Example of Selection.

A contributor to the *American Agriculturist* writes thus: It is the general testimony of those who have tried it, that the productiveness of seeds of many crops—among which may be mentioned wheat, corn, and potatoes—is greatly increased by changing their locality. Will it not be well for farmers to bear this in mind now, and not wait until some unlooked-for delay may chance to embarrass Spring work? Perhaps the benefit is not owing so much to change in latitude or longitude, as to change of soil. If not, then it will do as well to exchange with some neighbor who has seed raised on a different soil. But what has been proved, is safest, and those who can procure seed from a distance should do so. It is not too early to be looking about, and making arrangements to that effect.

[That to change the locality of seed is beneficial, seems to be the general opinion, and therefore it is reasonable to suppose there must be something in it, though we do not understand why this is so, nor are we certain that the popular opinion is not an erroneous one. On our old paternal homestead the same varieties of wheat, corn, and potatoes, were grown continuously, perhaps for twenty years or more, and instead of deterioration in quality or product, there was a constant improvement, so much so that most of the wheat raised was in demand for seed. A system of selection was followed. No potatoes smaller than hens' eggs, and no over-grown tubers, were planted. The seed wheat was obtained by hand-screening, with a sieve made specially for the purpose which retained about one third of the largest and plumpest kernels. The two-thirds passing through the sieve was still first grade in the market, at least after this selection of seed had been practiced a few years. Ed.]

Why is a woman mending her husband's clothing after he has retired to rest, like the enemy of the human race? Because she is sowing *tares* while the good man is asleep.

SPECIMENS OF GOURDS AT THE "AMERICAN AGRICULTURIST EXHIBITION."

1. Valparaiso Squash. 2. California Squash. 3. Hubbard Squash. 4. Crook-neck Squash. 5. Turban, or Turk's-head Squash. 6. Golden Winter Scallop. 7. Vegetable Marrow. 8. Green Striped Bush. 9. Lagenaria Vitata. 10. Gourd from Hindostan, new. 11. Mock Orange. 12. Pear Gourd. 13. Sandwich Island Gourd. 14, 15. Unknown. 16. Hercules' Club. 17. Artichoke Gourd. 18. Long Orange Gourd. 19. Cucumis Dipsacius, Japan. 20. Cucurbita Striata. 23. Bottle Gourd. 24. Boston Marrow Squash.

The Gourd Family.

Few persons, except professional seedsmen, have an idea of the number of varieties belonging to the gourd tribe, named *Cucurbitaceae* by botanists. Until recently, comparatively little attention has been paid to their cultivation, except in the case of the squashes and pumpkins, which occupy time-honored places in the garden and the field. Within a few years, fancy and ornamental gourds have been coming into favor for decorative purposes, and their number and beauty have been greatly increased by importation from foreign countries, and hybridization with old varieties. The recent exhibition of these vegetables at the Office of the *American Agriculturist*, called out a most beautiful display. About one hundred different kinds of the gourd family were represented, from the Mammoth Valparaiso Squash weighing 2704 lbs., to the diminutive striped gourd, that when full grown scarcely equals a black walnut in size.

The above engraving, drawn from specimens at our exhibition, shows some of the more curious and otherwise noteworthy varieties. Part of these will be recognized as established favorites in the garden and on the table: others are new and striking. The specimen numbered 5, the Turban Squash, bears a striking resemblance to a Turkish head-dress, and from its beautiful coloring is a most attractive object. It is also edible, and by some considered to be of fine quality. No. 13, the Sandwich Island Squash, was trained while growing, into a good resemblance to a swan without wings; the bill is well represented by the stem. No. 10, is a new and singular specimen raised by W. F. Heins, from seed sent to the *Agriculturist* office from Hindostan. From its pungent quality we suspect it belongs rather to the capsicum family

than to the cucurbitae. No. 19, might be called the 'vegetable caterpillar.' It is about three inches long and half an inch in diameter, of bright green color, and thickly studded with stiff hairy spines. It was grown from seed received from Japan. We have no knowledge of the use made of it there. It forms a unique ornament. No. 18, the long orange gourd with dark green bottom, is one of the most pleasing varieties for ornament. The vine trained upon a rustic trellis or over rock-works in some corner of the grounds, is a beautiful object when laden with its rich parti-colored fruit, and the gourds when ripened are very attractive. The markings of green are varied with each specimen, making them still more pleasing. The different kinds of gourds are so easily hybridized, that it is less difficult to procure an almost endless number of sorts, than to preserve any desired variety true to the original. It can only be done by covering the flowers designed for seed, with some protection against insects, and fertilizing them with pollen of their own species. A single bee entering a blossom may bring with him pollen from several different species gathered in other localities, and thus impregnate the flower and cause its seed to vary.

Attractive as are the ornamental features of the gourd family, most of our readers will be more particularly interested in edible varieties. For excellence both as a sauce and for pies, the Hubbard squash (No. 3 in the engraving) still remains at the head of the list. It has made its way but slowly into the markets. Its dark green color gives the idea of unripeness, and we have known parties growing it for the first time, to throw away the fruit and pronounce it a humbug, supposing the season to be too short for its maturity. But after having once become acquainted with its excellence, its color is no

longer an objection. Next to the Hubbard stands the Boston Marrow, already so well known as to need no description. With this, perhaps, even superior to it for pies, the African squash takes rank. It is much larger than the Marrow, but this is rather an objection for ordinary family use. One specimen could hardly be wholly used before spoiling.

The cultivation of squashes and pumpkins is not difficult, though a few important particulars must receive attention to secure the best results. Being mostly natives of tropical climates they should have a warm situation, as a southern exposure, or under protection of a building or high wall. It will be very advantageous to start them early in a hot-bed or in the house, and transplant them when they have attained the third leaf. Of course, there should be great care to leave the roots entire, and the earth around them undisturbed. An easy way of accomplishing this is to scoop out large turnips, fill them with rich earth, and plant one seed in each. When ready to transplant, cut off the bottom of the turnip, and the roots will soon find their way out; the remaining substance of the turnips will decay and feed the plants.

The best soil for growing these vegetables, is a deep, warm, sandy loam, well enriched with stable manure. Not only should the hill be made rich, but also the surrounding soil where the vines will send out rootlets to gather nourishment. Too little room is usually allowed to each plant. They need space enough to run without crowding and shading each other. The area required will of course depend upon the kind cultivated. It is a good plan to sow at intervals a number of extra seeds in each hill as food for insects, which will attack the young plants, and leave the first to grow too strong to be consumed by them; they can be easily thinned

out as needed. More minute directions for treatment of the vines will be given at the appropriate season, in our Calendar of Operations.

About Earth or "Angle" Worms.

The common earth worm (*Lumbricus terrestris*), has no eyes, feet, or other external appendages, and the head differs from the tail only in being more narrow and pointed. Its stomach consists of two pouches, and the alimentary canal extends from stem to stem. At about one third of its length from the mouth, there is a sort of belt, encircling the body, consisting of from six to nine rings, among which lie the organs of reproduction. As the worm is hermaphrodite, each individual carries this belt. It has the senses only of taste and touch, the latter being acute, as everybody knows who has touched it on peering from its hole. Its taste is coarse, since it feeds upon the soil it lives in, swallowing it and its half-decayed organic substances, and passing them through its body.

It is not certainly known whether these worms breed oftener than once a year. They produce their young sometimes from eggs, and sometimes already hatched. The eggs are laid at a considerable depth in the ground, and in clusters. They are laid mostly in the Spring, and hatched in June or July. The egg is about the size of a pea, elliptical, with a tubular hole at one end, through which the young escapes. In the cut annexed, *a* represents an egg, *b* the same after the embryo becomes visible, and *c* the same with the worm beginning to shift for itself.

The common notion that if this worm be cut into any number of pieces, each portion will live and soon become a perfect worm, is hardly true. But if any part of its body be cut off behind the belt, the remainder will be reproduced. If, however, it is cut in two at the belt, or between the belt and the head, it is sure to die.

The natural uses of the worm seem to be to furnish food for moles, frogs, toads, snakes, birds, fishes, and some kinds of insects. It is sometimes asserted that they are useful to vegetation, by boring the earth and loosening it, rendering it permeable to air and moisture, and even adding to the depth of the soil. But this is probably a mistake. The frequent boring of the ground makes the adjacent parts firmer. The worm-casts thrown up above the worm-holes are water-tight, and so prevent the descent of water into them. Their subsoiling does not amount to much. On the other hand, they do positive injury. They disfigure walks and lawns by their casts, and eat into roots of plants, especially those which are feeble.

These worms can be destroyed wherever they congregate in considerable numbers. As they are quite thin-skinned, any hot or caustic liquid will kill them. An excellent caustic is made by dissolving quick-lime in water, at the rate of half a pound of lime to six quarts of water, to be applied through a common sprinkling pot. Wherever worm-casts appear, sweep these off with a stiff broom, and then apply the caustic freely. In a short time, the worms will come to the surface, and die.

VARIETIES OF THE HORSE-CHESTNUT.—The number of species and varieties is greater than is commonly supposed. Beside the common one, with white flowers, tipped with pink, there is a scarlet, and a rose-colored, a double white,

Michaux's, Whiteley's red, a cant-leaved, and the common Buckeye. These belong to the genus *Æsculus*. If we include that of *Pavia*, which is smooth-fruited, we have a yellow-flowered, a red, a pendulous dwarf red, a downy-leaved, a purple, a flesh-colored, etc., etc. The scarlet is particularly fine. We have seen a striking effect produced by grafting the alternate limbs of the old white with the scarlet; the result was a brilliant, mammoth bouquet.

Important List of Pear Trees for the Vicinity of New-York, Ripening in Succession through 5 to 6 Months.

In the previous volume we have frequently referred to the Fruit Growers' meetings held weekly at the office of the *American Agriculturist*, on each Thursday at 1 o'clock P. M. Though almost entirely informal in their character, the discussions of matters pertaining to fruit growing have been highly interesting and valuable.

Several weeks since we suggested to the gentlemen present, the desirableness of agreeing upon a list of varieties of pears for family use—with some regard to marketing, and to ripening in succession throughout the entire season—which could be recommended at least for the vicinity of New-York City. The importance of such a selection was urged in view of the greatly increased general interest in fruit growing, and from the fact that the list of trees grown by nurserymen has become so extended as to require no little pomological knowledge to select a good assortment from their crowded catalogues. We also desired such a list as a reply to very numerous inquiries from our readers for a list of good pears for family use, and for market.

A competent Committee was appointed, and a request made that as many as could make it convenient should present lists of 20 varieties, with the number of each recommended to make up an assortment of 100 trees. Such lists were furnished at subsequent meetings by Charles Downing, Parsons & Co., T. W. Field, W. S. Carpenter, A. S. Fuller, Dr. Ward, J. G. Bergen, and others, all practical fruit growers of large experience. These lists were compared and their merits fully discussed at six successive meetings. The following list was finally agreed upon and recommended almost unanimously. Reference was had specially to varieties known to be successful in the region of country around New-York City, but the list, with slight modifications, is valuable for the whole country:

LIST ADOPTED BY THE FRUIT GROWERS MEETING.

2 Doyenne d'Ete.....	July 15 to Aug. 10
2 Beurre Giffard.....	Aug. 1 " " 15
4 Tyson.....	" 10 " " 20
10 Bartlett.....	" 15 " Sept. 15
4 Belle Lucrative.....	" 15 " " 15
6 Flemish Beauty.....	Sept. 1 " " 25
4 Louise Bonne de Jersey.....	" 10 " Oct. 10
4 Seckel.....	" 15 " " 15
4 St. Michael Archange.....	" 15 " " 15
6 Beurre Bosc.....	Oct. 1 " Nov. 1
10 Duchesse d'Angoulême.....	" 1 " " 20
4 Bergen.....	" 1 " " 20
4 Beurre d'Anjou.....	" 10 " " 25
4 Beurre Clairgeau.....	" 15 " Dec. 15
4 Beurre Diel.....	" 15 " " 1
4 Urbaniste.....	Oct. " " Nov.
4 De Tongres.....	" " Dec. 15.
4 Winter Nelis.....	Nov. " " Dec.
8 Lawrence.....	" " " "
6 Vicar of Winkfield.....	" " Jan.

The Urbaniste was adopted with the understanding that it comes late into bearing, and the De Tongres was added as promising exceedingly well, though not sufficiently proved to warrant an unqualified recommendation.

The Louise Bonne, Duchesse, Beurre Diel, and Vicar, were considered best on quince, while

Bartlett, Flemish Beauty, Seckel, Beurre Bosc, Beurre Clairgeau, De Tongres, Winter Nelis and Lawrence, were recommended on pear, or double worked on quince. The remainder of the list may be on either pear or quince.

At first, strong objections were raised against the Vicar of Winkfield, on account of quality, but these were over-ruled by those who explained that they were not generally well ripened. Some specimens exhibited, though prematurely ripe, were pronounced really fine, with a sprightliness not found in many other sorts. Pears of this variety should be picked late, put in a cool cellar or other place, and be kept until the first or middle of December; then after exposing for one week in a moderately warm room, they color up finely, and are of fine flavor at a season when but few others are to be had. They can be kept back until the middle of January. The Vicar is one of the most vigorous growers and constant producers of large crops that we have.

There was much discussion over the Beurre Bosc—the nurserymen, while admitting all its good qualities, say it costs twice as much to raise as many other sorts, and they fear if a person plants out two-year old trees, he will lose half of them, so difficult are they to carry through the first few years of growth. After becoming established, and especially on branches of large trees, this sort does pretty well, and the quality of the fruit is of such excellence, that it finally received a strong vote.

Persons wishing to plant 50 trees can take half the various kinds named in the above list, or if they do not wish so great a variety, let them select from those having the highest numbers, keeping in mind the succession in maturing.

For Peach Trees.

A correspondent of the *American Agriculturist* writes thus: B. F. Seaver of Orange Co., N. J., whose peach trees had not borne fruit for several years, had a good crop the past year, some trees yielding 3 to 4 bushels each, and the trees were very thrifty. He attributes his success to the application of a method recommended to him by Mr. Plummer of Newark. In early Spring, as soon as the frost began to come out of the ground, a teakettleful of scalding-hot water was poured over the crotch of each tree, (the crotch being generally not far up from the ground.) The water circulating round the trunk enters the ground, and kills the gnubs which produce the "yellows" later in the season. A small puddle hole in the ground around the base of the trunk should first be made, to hold the water as it falls, and if you will examine afterwards, you will find the dead worms. You can't have the water too hot, and need have no fear of injuring the bark of the trees. Of course the excellent fruit season had much to do with the large crop realized last year, but as several duplicate trees of previous years, in the same locality, had died of yellows, it is reasonable to suppose the above operation had a good effect. [We can not affirm that the hot water was useless, but we can hardly see how it could be beneficial. It could not of course run up into the holes of borers, and if it did, it would not be hot enough to disturb them after running down the trunk. Other insects would hardly be found on the surface at a time when the frost is just coming out of the ground. A continuous stream of hot water would be likely to soon destroy the vitality of the bark. Perhaps we are wrong, but without the success of the method in other years than the past one, we should not recommend it for general adoption.]

Curious Trees.

Useful trees have their place, and so do ornamental trees. But in addition to these there is a class which may be called distinctively *curious*; and of these a few notes may be interesting:

The *Cow Tree* is a native of Venezuela, South America. It is often found growing on the poorest and most rocky soil. Its leaves are dry and leathery in appearance, and for several months of the year not a shower falls to moisten its roots and branches. Yet, by piercing the bark, it yields a liquid resembling milk, which is sweet and nourishing. At sunrise, this fluid seems to be especially abundant, and at this hour the natives go to the trees in great numbers to get their daily supply.

The *Sorrowful Tree* is found near Bombay, India. It is so called, from its habit of blooming only at night. While the sun is shining, not an expanded flower is visible; yet in half an hour after the sun is below the horizon, the tree is full of them. There is little beauty in them, though the odor is pleasant. At sunrise, the petals close up or drop to the ground. This tree, it would seem, must have some sort of relation to the night-blooming Ceres.

The *Dwarf Tree* is found upon high lands near Cape Horn. Its maximum height is two and a half feet, and the spread of its branches about four feet, and a stiff, thorny mat at that.

The *Mammoth Trees* of California, are worthy of note here. They are found three hundred feet high, and 29 feet in diameter at five feet from the ground. A hollow section of a trunk was lately exhibited at San Francisco, which presented a large carpeted room, with a piano and seats for forty persons. On a recent occasion, one hundred and forty children were admitted without inconvenience.

The *Ivory Nut Tree* is found in South America, and belongs to the palm tribe. The natives use it in building their huts, and out of its nuts they make buttons and various trinkets. Of late years, the nuts have found their way to other countries where they are worked up into all sorts of fancy articles.

The *Cannon Ball Tree*.—What can be more interesting than this tree in our warlike times! It's a pity that it grows only in the tropics. It rises about sixty-five feet high, has beautiful crimson flowers, in clusters, and very fragrant. The resemblance of the fruit to cannon balls has given it its martial name. When fully ripe, the balls burst with a loud report. The shells are worked into cups and a great variety of other useful and ornamental household utensils.

The *Bread Fruit Tree*.—Here is something useful, as well as curious. Would that it grew somewhere besides in the islands of the Pacific. The fruit attains the size of a child's head ten years old. If wanted for food, it needs to be gathered a little before it is fully ripe, and then baked, like hoe cake, in hot ashes. When properly cooked, it resembles not a little the taste or a good wheaten loaf. Nor is this the only use of the tree. Its timber is excellent for house-building, for making canoes and agricultural implements. The sap is a gummy substance, very useful as a pitch for caulking the seams or vessels. The fiber of the inner bark is used by the natives for making cloth, which in that climate answers a good purpose. It is the favorite tree of its native region; and well it may be.

The *Upas Tree*.—The "deadly Upas," of which we have all read and heard from childhood, which was supposed to diffuse a poisonous air, fatal to animals or men who came beneath its

branches, has no existence, and never had. The only possible ground for the superstition was this: On a certain island of the East Indies, there is a valley in which there is a constant deposition of carbonic acid gas. This gas spreads itself among a few trees of the neighborhood, and of course, if birds, animals or men inhale much of this gas, it will quite surely be fatal to them. But this is no fault of the trees, which have been found to possess no poisonous quality.

The *Tallow Tree* is a veritable fact. It lives in China, and yields an oily substance resembling tallow, and which answers well as a substitute for it. The tree is of only medium size, at maturity. It would not be hardy in America.

The *Varnish Tree* is Japanese, though found, also, sparingly in China. This is the tree which produces the black Japan varnish, so useful an article of commerce. It resembles, in general appearance, the white ash tree of this country. It does not furnish its peculiar liquid in large quantities, until nine or ten years old.

Tree Planting Societies.

Several years ago, mention was made in the *American Agriculturist*, of a Rural Art Society established in one of our towns, the leading object of which was to encourage planting roadsides and yards with shade-trees, and to foster a general public taste for rural improvement. This article was copied into an influential paper in London, with a commendatory note by the Editor. A year after, a gentleman who had read the article, was led to recall and re-read it. His reading set him a-thinking, and his thinking set him a-writing. He wrote several articles, urging the rural embellishment of London and the surrounding villages. Other pens became enlisted in other parts of the kingdom, the subject got a good airing, and something practical is likely to grow out of it.

One of these articles urges the formation of rural societies like those in America. Here are a few sentences: "The idea of promoting these objects by an association is a happy one; and in this age of co-operation, such a society can easily be established. Owners of property in and around villages would belong to such a society, because the embellishment would enhance the value of their property. Men of taste would belong to it, for the gratification it would afford them," etc., etc. So it would seem that the good seed sown by our agricultural papers, often springs up and bears unexpected fruit.

For the *American Agriculturist*.

A Farmer on our Native Forest Trees.

MR. EDITOR: It seems to me that there is too much of a rage for foreign trees and plants, to the neglect of the productions of our own country. I know, indeed, that *all* the good things are not confined to this nation, but I believe we have enough for our own use. Not a few persons are fond of having a root or cutting of something which once grew on a famous man's estate in England or France—no matter whether it is adapted to our climate or not. They are forever hunting after something rare, something uncommon, something which ordinary people can not hope to possess.

Now, I go in for the natives. We have here at home enough, and more than enough, to satisfy every reasonable desire and taste. If a person wants to increase his variety, here is opportunity enough. The fact is, only a few persons know what a long and varied catalogue we pos-

sess. The planters and nurserymen of England and the Continent are continually sending over here for our trees and plants, knowing them to be the finest that the world possesses: but are they not as good for us as for them? If you should send an order to any intelligent nurseryman in England, for a dozen of his best ornamental trees, irrespective of their origin, and adapted to a northern climate, rest assured he would send you, among others, the cucumber tree (*Magnolia acuminata*), the tulip tree, white elm, sugar maple, hemlock, and white pine, all of them indigenous to North America. That's worth thinking about.

Then, there is a certain claim of self respect. If a person is continually undervaluing his own, and hankering after the things which others possess, it indicates weakness, and it lowers him in the estimation of others. Now, if we respect ourselves as Americans, I think we shall put a due estimate on our own possessions; we shall feel a sort of national pride in them. For one, I feel proud of whatever belongs to us as a people. Our country, in its vast extent and resources, in its scenery and climate and people, is one of which we may well think highly. Our civil and political institutions cost us a great deal to purchase, and now, much more, oh, how much, to maintain and preserve! Now, sir, I can't help appropriating somewhat of this national feeling to our native productions—to our very grasses, and grains, and fruits, and trees. I dearly love them, because they belong to my own native land. Let us all prize, more and more, the trees which clothe our hills and adorn our valleys, and the vines, shrubs, and plants, which smile all over the landscape. FARMER.

Hints from Mr. Loudon.

In turning over an odd volume of Loudon's Magazine, lately, we met in his description of a country seat, a hint or two worth recording:

"Here we found *Thunbergia alata*, in great luxuriance, sowing itself every year, a proof that it may be treated as an annual. *Maurandya Barclayana* here, as in some other places, is found to be perfectly hardy. The top dies down to the ground in the Fall, but new shoots spring up vigorously in the Spring. And this we presume will prove to be the case with a multitude of other plants which we have not tried.... The collection of choice shrubs and ornamental trees here is remarkable, considering the limited extent of the place, the secret of which is, that few common plants or duplicates are admitted.... There is not a greater mistake, in planting pleasure grounds, than the mixing of the common or indigenous shrubs of the country with foreign or improved species. It is as bad in a garden, as it would be in architecture to mix Grecian ornaments with Gothic ones." He also speaks of thorns being tied around the stems of young trees to guard them from animals. Also, of certain plants which require an abundance of light, but can not endure the direct rays of the sun; these are accommodated by being set where they get only the light reflected from a high wall which had been whitewashed. Query: Would not this answer for rhododendrons and laurels?—Lastly, he publishes the letter of a head-gardener who, in speaking of the trenching of the ground done for planting a lot of young magnolias, says: "The subsoil on this place we have not yet been able to prove, never having gone down deeper than five feet; but to that depth, it is all sandy loam." Think of that, ye American trenchers! Only five feet down!

Land on Slopes of Steep Hills.

A subscriber of the *American Agriculturist*, in Pittsburg, Pa., inquires "what to do with a plot of ground on a hill side, above a stone quarry that prevents building a stone wall around it. It has a stiff clay subsoil, resting on a layer of red greasy clay. The surface soil is inclined to 'slip,' but if it can be improved it is valuable for a graper."—Probably bastard trenching, that is, digging it deeply but not inverting the soil, and placing under-drains and surface drains so as to carry off washing water, would put it in shape for tillage. The grape vine roots, after once filling the soil, would help keep it in place. In some favorite grape localities along the Rhine, where peculiar qualities of wine are produced, but where the surface lies but a few degrees from a perpendicular, they even go so far as to place baskets of earth among the stones and rocks, and fill up between them with soil. The baskets hold the earth until the grape roots spread, and take their place as they decay.

On the steep side hills around Stuttgart, in Wurtemberg, in many places along the Rhine, and among the hills between Lyons and Geneva, and in other places in Switzerland, France, and Germany, we examined vineyards upon the sides of hills that were naturally so steep that one could scarcely climb them. The usual method pursued is, to build stone walls along the hill, a few feet or rods above each other, and level off a plot of soil between the walls, making a succession of terraces. Stone and bush drains are provided to convey currents of water that would otherwise wash down the soil. On the steep, high hills overshadowing Stuttgart on the south, the terrace walls are of almost regular solid masonry, with cut-stone gutters to convey the water. The cut-stone steps leading up through the plots are in many cases laid solid, and hollowed out to serve as water courses during heavy rains. Large sums have been expended in thus making artificial soils, but the luxuriant crops of grapes, such as we saw growing, doubtless pay a good interest on the original outlay. These steep hill sides, especially when the soil is worked deep, and thus thoroughly drained as it must necessarily be, seem to be just the places grapes most delight in. There are many such localities in our country. Hill sides, now worthless, may be fitted up for vines, with little more labor than it would pay to expend on any soil devoted to successful grape growing. Any suggestions on this topic, such as would help our Pittsburgh correspondent, and others similarly situated, will be acceptable.

A Compliment from John Bull.

In these days of trial, when England turns the cold shoulder to us, it is comforting to recall the pleasant things she has said and done in former times. Here is a morsel: Several years ago, when Mr. Loudon was giving instruction to a committee of gentlemen in reference to the embellishment of a public park, he said: "In that portion of the Park where it is desirable that the greatest beauty and interest should be created, the trees of North America should be planted. To these may succeed the trees of Greece and Italy; next, those of France and Germany; then, the British trees; and lastly, those of the north of Russia, and of Sweden and Norway."

One would have thought that British trees would be placed high in the list; and that those of the classical lands of Rome and Greece, if

not also those of France and Germany, would precede those of our own wild, democratic country. But lo! our trees are put at the head of the catalogue of all the nations!—How about our *men and women* raised on the soil that grows these trees?

For the *American Agriculturist*.

On Fitting up a Home—Confessions of an Amateur.

Every fruit grower and gardener has to educate himself, and generally pays very dear for his education. Multitudes get possession of the house, and a home lot, and the means to adorn it, before they get the knowledge requisite to lay out their money to good advantage. Many go ahead without consulting architect, artist, or gardener—build, lay out grounds, plant trees—for it is the weakness of a Yankee to the manor born to think that he can do almost any thing as well as if he had never done anything else. Such go-ahead improvers after a few years' labor begin to get hold of the principles of landscape gardening, especially if they travel much, and observing other well kept places, discover that they have made several blunders, if not more. The gate is in the wrong place, the carriage drive has taken the wrong turn, the Norway spruces hide objects that ought to be seen, and a good deal is brought into view that were better hidden. He has at length educated his taste so that he can enjoy nothing that he has done, and he has to "change his base" and begin again. The walks are moved, new hedges are planted, half grown trees are transplanted, some are cut down, fruit trees are thinned out, and the work of years is destroyed in a day. Many can never summon resolution enough to make the change, and go on cherishing the blunders of their early years. They have gained a good deal of knowledge by their experience, but it comes a little too late for them.

I do not come altogether under this latter category, for I have already changed many of my blunders, but a few, alas! must remain for another generation. I am willing to put some of these blunders upon record for the benefit of those who are just building new homes or beginning to improve them. First, then, is the neglect of the architect and the landscape gardener. There is a wide spread prejudice against these characters, probably from the fact that both professions have their unworthy representatives, miserable pretenders who do not understand the first principles of their business. But Downing has his worthy successors, and the man who wishes to avail himself of their aid, can easily find them. Two or three hundred dollars seems a large outlay for the plan of a house and outbuildings, but in an expenditure of fifteen or twenty thousand dollars, or even half that sum, it is of trifling importance. The plan determines the character of the house, and the comfort of the household for their whole lives. A door in the wrong place, or the want of one in the right place, is matter of daily annoyance. Bad arrangements in the kitchen and dining room make a great deal of unnecessary labor for which you have to pay. The lodging room and nursery upon the second or third story, instead of the first, make a multitude of weary footsteps for the wife and mother already overtaxed. The continued health of a wife and well being of children may depend upon so small a matter as the right location of a bedroom. No rewards are better earned, none are cheap-

er to the purchaser, than those of the architect who plans a house to meet the wants of your condition in life and your family. The problem to be solved varies with almost every family. It is the business of the architect to study these wants and to meet them in the most economical manner. Many, more than save the price of their services in the increased economy which they secure in building, and in the future labor in the household. Some houses are so badly arranged that it requires three servants to do the work which two would easily perform in another.

The arrangement of the grounds around the dwelling is another, of less importance indeed, but still not to be overlooked. Every gem wants its appropriate setting, and a tasteful house may be half spoiled by its surroundings. We want the apples of gold in pictures of silver. Trees and shrubs may be so planted as to lighten the charms of the dwelling, and to give it additional shelter and warmth in Winter. They may be so arranged as to command the most beautiful objects in the distance, or to obstruct the view. One of my neighbors has entirely buried himself up in his trees. His home stands on an eminence commanding a beautiful view of the distant sea and its islands, but he can not see a sail from the window of the sitting room, where the family spend most of their leisure hours. The windows look out pleasantly upon a lawn of four or five acres. But a large clump of evergreens completely obstructs the view. He is sheltered indeed, but he has cut off the cheerful light of the sun, and the pleasing aspects of nature around him. He might have bid defiance to the winds, and at the same time have wooed the sunlight. He is surrounded with green fields but he can hardly get a glimpse of them.

This may seem to be a small matter to people without taste, but it has a good deal to do with the happiness of the family. We ride miles to get a pretty view from the summit of a hill, and enjoy the whitening sails of the sea, or the steamers that leave behind them their long trails of smoke. Such a view, or any other pleasing prospect, would seem to be worth preserving at home. I am a little old-fashioned in my tastes, but really, I prefer to have these pictures out of doors, rather than their imitations upon the walls of the parlor.

Twenty years ago, I planted a clump of evergreens, mostly Norway spruces and hemlocks, to hide a neighbor's barn across the way. They have grown wondrously, and more than accomplished their object, for they have hidden a glimpse of a sheet of water that lies at the foot of a hill a mile away. The trees are too beautiful to be cut away, it would be sacrilege to trim them, and I am in a quandary to know what to do with them. In tree planting, one needs to look ahead a little, and see what a tree will become when it is well developed. Smaller evergreens would have hidden my eyesore, and saved my lake. HENRY HERBERT.

Culture of the Pansy.

Few flowering plants give greater satisfaction than the Pansy. Less brilliant and showy than the verbena, petunia, scarlet geranium, and the like, it yet has excellences to which they can lay no claim. It is easily cultivated, requires little or no protection in Winter, commences blooming early in Spring, and with a slight check in the heat of mid-summer, continues in flower all the season, and furnishes an almost endless variety of colors, shades and markings. In answer to many inquiries about the prepa-

ation of the soil and general management, we quote from an English work on the Pansy, which is the highest authority in that country: "The results of various experiments relative to the growth of this flower, amount simply to this, that to produce fine, large blooms, due attention must be paid to soil, situation, and often transplanting. Young plants are generally found to produce the largest and finest marked blooms.

Soil and Situation.—Pansies delight in a cool, shady situation, and in a light, rich, loamy soil. A composition of good loam, enriched either with rotten dung, or leaf or vegetable mold, will grow them in the highest perfection; yet they will grow well in any good garden soil. But by using proper earths, often transplanting, and due attention to shading, situation and watering, you may have a succession of fine, large blooms for nine months of the year." (Nine months of the English year, of course, but not of our colder country and of our shorter season.)

To the above, we will add that, in our own experience, a deep soil, enriched heavily with well decayed cow-dung, mixed with a little sand, leaf-mold, and common earth in equal portions, makes the perfection of soil for this favorite plant. Shade, for part of the day, is quite desirable. The seed may be sown in the open ground, in September, where they will get a good start before Winter sets in, and they will make a fine show the following season. Or seed may be started in March or April in boxes in the house, or in a hot-bed, and then transplanted into the border as soon as Spring fairly opens. They should be set a foot apart in the beds, at which distance they will soon cover the ground.

A New Convolvulus.

The engraving above will give some idea of a new trailing plant from southern Europe, recently introduced into florists' collections. It is known in the catalogues by the alarming name *Convolvulus Cantabricus stellatus novus*—in plain English, the new Spanish Star Morning Glory. The flowers are of a beautiful, soft, pink color, with a pure white double star in the center, and being produced in the greatest profusion, it forms a fine bedding plant, either as an edging, or in an isolated bed. It is peculiar-

ly adapted for vase edging for rustic stands or boxes. The most pleasing disposition of it, however, will be in a suspended pot or basket in the sitting room, where its bright petals and gracefully drooping runners will give a charming aspect of cheerfulness. It is said to be

vines and flowering plants mingled together, each striving for the mastery; but a flower garden is, and should be, something quite different from natural scenery. It is designed to cultivate plants better than when growing wild. Every experienced gardener knows that few

plants attain perfection when overhung and shaded by trees, or in a soil penetrated by their roots. But this is the condition of many herbaceous plants when set in borders partly filled with shrubbery. They become drawn up, lank and spindling, or one-sided, and they make a comparatively feeble growth. Yet, how could this be otherwise when the soil is exhausted by the rank-feeding bushes? And besides, there is no harmony of effect between trees & shrubs. For illustration, take an extreme case: A tree awakens the idea of dignity and grandeur. One needs to stand at some distance to examine and comprehend it. The expression of an herbaceous plant in bloom, is that of brilliancy of color, and beauty of detail, and the eye must be brought near to examine it. To enjoy trees, one must look up; to enjoy plants he must look down. The parallel holds, somewhat, between shrubs and plants. The works of the best artists are marked by unity of design; so will the works of the best gardeners be. If we want to enjoy trees and shrubs, let us have them grouped by themselves; and the same of flowers.

And here let us say, that too little attention is given to shrubs. They are beautiful in themselves, and they form an appropriate link be-

tween trees and plants. Their habits, as to light, form, color, etc., should be made a continual study, and their arrangement, in groups and scattered specimens, should be as carefully planned as that of trees. They may be set in grass-ground, if the soil is kept well stirred around them a few years, until they are firmly established; after this, the grass may be suffered to grow up to their stems. They should be set at suitable distances apart, to allow of their full growth without becoming crowded into a confused, ill-shapen mass, as in a wild scene. It was a standing rule of Mr. Loudon, that "as a garden is a work of art, and a scene of cultivation, every plant or tree should be so placed as never to be mistaken for a tree or plant placed there by accident, or so as to prevent the prac-

NEW PLANT FOR HANGING BASKETS.

(Engraved for the American Agriculturist.)

very easily cultivated in good loam with the addition of a little thoroughly rotted leaf-mold.

The rustic basket containing it, shown in the engraving, is worthy of notice. An almost endless variety of designs for such receptacles can be made of twisted pieces of grape vines, gnarled branches of oak, irregular roots of various sorts, etc. These, neatly varnished, will be more pleasing than the most costly vases.

Mixed Flower Gardens.

It is a great mistake to mix shrubs and herbaceous plants in the same beds. They can not thrive well together, and the one injures the effect of the other. It no doubt looks very picturesque, in a wild wood, to see trees, shrubs,

tices of good cultivation from being applied to it." This is a very good rule for the planting of shrubs and flowers, as well as of trees.

Large Rhubarb from Seed.

Hugh Miller, of Charlevoix Co., Mich., wrote to the *Am. Agriculturist*, Oct. 11: "The Linnæus Rhubarb seed received through your Seed Distribution in the Spring, was planted in common garden soil of fair quality, and appears to have produced two or three new sorts. The largest kind is a dark green, and some of the stalks measure, at this date, 12½ inches from the ground to the leaf, and 4½ inches in circumference at the bottom. The stalk is round on the under side, and flat above. The leaf is 20½ inches long, and 21½ inches across."—This is certainly a remarkable growth from seed the same season. As we distributed many thousands of packets of seed, it is quite likely that several improved seedlings have been produced which will be worth propagating and diffusing elsewhere. The quality of the stalk, or of its juice, as well as size of growth, must be taken into account in deciding upon the merits of the new seedlings.

THE HOUSEHOLD.

Smart Parents have Dull Children.

The truth of this, as an almost universal rule, can be substantiated in every community. We should naturally expect the contrary. Striking characteristics are, in part at least, transmitted from parents to children. Why then, do so few sons and daughters of intelligent, active, and successful parents develop equal energy and achieve equal success?

Probably the following suggestions explain the difficulty and indicate a remedy. With rare exceptions, a man's success depends less upon his natural abilities and opportunities, than upon his self reliance, and consequent exertion of his powers. These traits are mainly developed in youth. Take an illustration. We have a friend, an equal partner in a firm doing business in one of the large marble blocks in this City. His natural intellect is not above average. Left an orphan at the age of four years, he fell into the hands of an uncle who was strict to austerity in his moral rule, but otherwise careless, and the boy was left mainly to shift for himself. To obtain pocket money, and much of his clothing, he peddled apples, gingerbread, etc., at shows, general trainings, and similar gatherings, and also made and sold various simple mechanical articles. The strict discipline of his uncle kept him out of vice, but the necessity of depending upon his own exertions, and the early practice of laying out his own plans and enjoying their results, developed ingenuity, foresight, and self-reliance. At manhood he came to New-York and entered a store as porter. His strict moral habits, and his developed abilities, were soon noted, and he was made clerk in the packing department. From this he was promoted to the selling, and then to the purchasing department, and upon the death of one of the partners, was gladly taken in as one of the firm. His business abilities, with his small savings, were considered a full equivalent to the greater money capital invested by the other partners.

Thus it has been in numberless instances. The children of the poor, thrown upon their own resources, have risen to competence and wealth. Their disadvantages have educated their abilities. But what has this to do with the subject of the present article? A good deal. Those parents who are "smart" themselves, generally do most of the work themselves, or at least take the whole direction of it. That active mother finds it easier to do her housework, than to leave it to the daughter. The daughter knows that mother will look after it, and exercises no care or oversight. The father looks

after every thing himself. The son is a mere machine worked by the father, and thus he grows up, incapable of successfully directing his own powers. Though naturally sharp, his faculties are dulled by inaction, and inherited talents are of little avail.

Our opinion is, that while parents should abate nothing of strictness of discipline in general matters, they should throw their children more upon their own resources. Let the son have his plot of ground, his animals, his own personal property, entirely under his own direction, for the care of which he shall be wholly responsible, and upon the proper management of which shall depend somewhat of his own pleasure and profit. Let the daughter at an early age have the oversight of certain departments of household labor, particularly those which relate to her own comfort. Let them thus grow up habituated to the exercise of their own thinking and planning powers, and their natural abilities will develop and give them a measure of success in adult years, which will do credit to their inherited talents.

About Pocket Handkerchiefs.

The pocket handkerchief, though not a prominent article in the outfit of a lady or gentleman, is yet worthy of some little attention. Care, but not fastidiousness, in minor points, marks refinement in either sex. It would excite ridicule for a well-dressed lady to display an old-style cotton pocket handkerchief, blazing with red and yellow devices, such as are in great request at the South for turbans for the negroes; and all the more justly, because a neat linen article can be had at no greater cost. To make the apron, or the fingers perform the service required of a handkerchief, is an abomination not to be tolerated in decent society.

For persons afflicted with catarrh, silk handkerchiefs are preferable to linen, being softer, and less apt to chafe the skin; they are also more serviceable. Care should be taken not to keep them in use an unreasonable length of time because they do not

easily show soiled places. They collect dust and other matter offensive to cleanliness as readily as linen, even if it be not manifest to the eye.

A neatly ornamented border or marking for the handkerchief for ladies is desirable. Expensive lace edgings and exquisite needlework, costing large sums, only show a love of ostentatious display, not in accordance with good taste. Accompanying this article are several original designs for ornaments around the name, or initials of the owner, to be marked upon the corner, which will be acceptable to the ladies. These designs can easily be traced upon the linen with a fine-pointed pencil, by laying it upon the paper, and holding it against the window pane. Afterward they can be readily worked with the needle, or drawn with indelible ink.

A CHILD allowed to govern those who should restrain him in infancy, will usually grow up without

the power of self-government, and he a slave to his own passions, or the tool of designing men.

Children on the Floor.

The floor is *always* the coldest part of a room in the first story, except in the few instances where the cellar contains an unshielded iron furnace that heats the whole air there, and the floor above.—In our own dwelling we use just such a furnace, at the expense of extra fuel, and to the detriment of vegetables and food stored in the cellar, *because* by this means the floors of the room above are kept warmed for the baby and the smaller children, and for the feet of all, young and old. Another cellar is used for the storage of most vegetables and fruits.—When the sun is shining into a room, stir up a little dust, and observe the currents of air. It will be seen that the warm air from the stove or register constantly rises toward the ceiling, while the cold air from the cracks and crevices about the doors and windows flows downward and *along the floor*. Young children, therefore, when sitting or frolicking on the floor, are in the coldest part of the room. The feet of those sitting or standing, are also the coldest. If, added to this, there is a cold cellar, or cold current of air beneath the single layer of boards in the floor, it is no wonder that the hands and feet and bodies of children get so cold, while the persons sitting or standing feel comfortable. There is perhaps no help for the currents of cold air; but when the baby is set on the floor, or the youngsters are playing there, they may be made more comfortable by spreading an extra carpet or piece of drugget, or even a blanket under them. In the morning, and whenever the fire gets low, or the floor, or the air of the room is unusually cold, the children should be elevated—the babe in the crib, and others on chairs. Every lady knows that her feet are warmer when placed on a foot stool, even if but a few inches high, than when they are upon the floor. The higher position of the head, neck, and arms, explains why these are warmer than the lower extremities, though the latter are well covered, while the former are bare. This may seem a small matter for discussion in the *Agriculturist*, but on attention to such little things much of our comfort and health often depend. At any rate, while you yourself feel warm, don't forget that the baby on the carpet is in a colder region, and may be actually suffering while you are warm.

Boots and Shoes—Warm Feet.

Those who have half a dozen active children, more or less, to keep shod, have probably found out ere this, that leather has gone up in price almost (but not quite) as rapidly as printing paper. If any one can tell us how to get cheap shoes, or any kind of shoes that will not cost about a dollar a month for each youngster, he will confer a special favor, and we will hasten to publish the fact for the benefit of the rest of mankind. Much can be done to lessen the expense of shoe leather, even at the present prices, by judicious selection and proper care of boots and shoes. A great mistake is made in buying thin shoes, with thin soles, for girls, while boys are provided with thick-soled high boots. A pair of strong boots will last a girl longer than several pairs of thin ones, and will allow her to enjoy the air and exercise which are necessary to health. There is no reason why the feet of girls and women should be more thinly clad than those of boys and men—"Fashion kills more than the sword."

Some of the means taken to preserve leather are injurious to it, while others are injurious to the feet. It is not desirable that a boot should be thoroughly waterproof; when this is the case, the perspiration is confined, and the feet rendered uncomfortable and unhealthy. The "waterproof or varnish blacking" so frequently used, is injurious to the leather, rendering it less pliable. It confines the perspiration, and keeps the feet cold by making the leather and stocking better conductors of heat. All those preparations which claim to render leather waterproof should be discarded. The

method which we have found most satisfactory is to apply melted tallow freely to the soles of the boots and shoes, and to the upper leather about an inch high around the soles. In this way the greater part of the upper leather is left in its natural condition, and will allow the perspiration to escape through the pores, while the soles are kept pliable and waterproof. The application of hot tar, as recommended in an article going the rounds of the press, makes the sole leather stiff, and, being unyielding, it wears off in contact with stones and frozen ground more rapidly than when rendered pliable by tallow. Neat's foot oil, when accessible, is preferable to tallow. When one is walking or working in deep snow or mud, it may be necessary to apply a single coat of grease or oil over the whole upper leather. We have found from experience that ungreased boots and shoes last much longer, and are more comfortable than those made air and waterproof by oil or by impervious blacking.

"Keep the head cool and the feet warm," is a trite prescription for health. The feet are always in a colder atmosphere near the ground, as well as exposed to dampness; and, worse than all, a foolish Chinese fashion, requires them to be cramped in shoes too small to admit free circulation of the blood which is the source, or rather the conveyor of animal heat. Special care is therefore needed to keep them warm. India-rubber overshoes are very good if worn only out of doors, and removed when coming in. Sandals, open over the foot are best, except when obliged to wade in snow or mud. Nothing contributes more to health and comfort than a frequent change of stockings. When stopping exercise at the close of a day's work, we invariably remove the socks filled with perspiration through the day, and put on dry ones for our long ride home to the country. Much comfort, and greater freedom from cold has resulted from this practice. The current opinion, in some parts of the country, is, that wet socks should be dried on the feet. This is not philosophical.

Humbug Doctors.

We are heartily tired of answering private letters inquiring about the character of this, that, and the other New-York "Doctor," whose flaming cards fill up so many columns of the papers, (often unpaid for,) and whose circulars are sent broadcast over the land. There are electrical doctors, Indian doctors, doctors of eyes, doctors of ears, doctors of "specific diseases" of the male sex and of the female sex, doctors of the feet, corn doctors, and more abundant than all others, the lung doctors. We do not advertise their cards, though frequently offered large sums to do so, and it is hardly fair that we should be called upon for so much time in investigating and replying to particular cases. Let us say, once for all, to the readers of the *American Agriculturist*, that we do not know a single one of these large advertising so-called "doctors," whom we would employ in any case ourselves, or recommend to others to do so. The half of them are not to be found at home when we hunt for them; and the other half are charlatans, who seize upon some particular ailment, and announce themselves as Specific Doctors for that disease. Their operations are carried on mainly through the mails. Some have an office or rooms, and by artful words beguile their patrons into submitting to their operations, after paying well for it. As a rule, those who make the greatest show in advertisements are the veriest quacks, without skill or ability to succeed in regular practice. Not a few of these are seapraggers, figuratively, if not literally, kicked out of the back door of medical colleges, for lack of application to study, or for other just causes. We may say more on this point, but one illustration will serve now: A family had a son who began to be a little hard of hearing. Seeing a spread-eagle advertisement of a Specific Ear Doctor, the parents opened a correspondence with him, and were by his letters, exciting their fears, and parading his own superhuman skill, induced to take the boy three hundred miles, and stay several weeks. Cer-

tain mystical applications of an electric machine were made daily for a month, and the parents and child were kept away from home at a heavy expense. After making a sufficient show to warrant him in charging \$150, the so-called doctor applied a mysterious wash, and in an hour after, the deafness was gone. The parents went home joyful, though it had cost them the savings of several years, and much disturbance of their business for the season. Why should they not rejoice, when their only son had been restored to soundness. They proclaimed the doctor's skill, gave him a glaring certificate, and induced others to follow their example. Now for the secret. The electrical applications were all a sham, used for effect upon the parents. The drums of the boys's cars had become a little thickened with wax, and incipient deafness had resulted, the same as if they had been filled with cotton. The mysterious ear-wash used in the end, was simply a little warm soap and water, which washed out the wax, and restored the hearing. Any half-skilled country physician, if applied to, could have discovered the cause, and prescribed the simple remedy. We notice by advertisements in our exchanges, that just now a large number of these quack doctors are perambulating the country, stopping a day or two at a time, now here, now there—just long enough to gather up the spare money of the credulous, nervous people, and then they are off. A few temporary stimulants, and the faith of the people in pretentious advertisements, give them a temporary credulity, and then they take care to get out of reach of their victims. We caution our readers against any faith in "Electric Physicians," *et id omne genus*.

Gizzards—Teeth—Stomachs.

Plato having defined Man to be a "biped without feathers," Diogenes threw before his pupils a plucked fowl, saying: "There is Plato's man."—Notwithstanding the fact that the *Agriculturist* has Diogenes *redivivus*, as a critic, we shall venture an improvement upon Plato's definition, thus: "Man is a biped without feathers and without a gizzard." This definition applies to man as he is constructed, though not perhaps as he ought to be. Indeed, most people seem to act upon the idea that Nature has made a mistake in not placing a gizzard at the entrance to the stomach; rather they act as if there was one really there. Let us see:

The stomach is a receptacle with soft thin membranous walls, fitted for holding and dissolving food after it is reduced to a fine pulpy state. In this organ the food, if properly prepared previously, is mixed with a fluid called gastric juice; then it passes into the duodenum, (the little stomach or enlargement of the upper intestine) where it is mixed with bile from the liver, and with the pancreatic fluid. These fluids combining with the nutritious portion change it into chyle or a milk-like fluid. As the food moves on through the 25 feet of intestines, the chyle is extracted by myriads of little tubes with mouths opening upon the inner surface of the intestine. These tubes convey the chyle into a receptacle in front of the spine, near the small of the back, whence it is carried by a larger tube and poured into the blood in a vein just below the left collar bone. The blood distributes the nutriment to all parts of the body as needed. But suppose a piece of meat, or a lump of potato, or of apple, the size of a large marrowfat pea, happens to get into the stomach. Having no crushing power, it can only roll the lump over and over, wearing and dissolving off a little from the surface, perhaps. The food heats and sours, if not dissolved, producing pains and dullness, and heartburn, and if there be much of it in this condition, sickness and vomiting, followed by a natural effort to eject the irritant. But usually, the undissolved lumps pass on after a time, and make their way through the entire intestines. As these have a peristaltic or worm-like motion, they are constantly irritated by contact with the hard substances, producing pains, colic, inflammation, resulting often in diarrhoea, or perhaps in dysentery. Every lump of food voided in an undigested condition has been a source of derangement—per-

haps not serious to a vigorous person, but still injurious. Most of the headaches result indirectly from undigested food in the stomach or intestines. But a gizzard at the entrance, with its strong hard sides and supplied with gravel stones, would mash up the lumps, and leave the stomach to go on with its natural functions; more nourishment would come from the same food; heartburn or stomach-ache and irritation of the bowels would not usually be produced. Fowls swallow their food whole, and the gizzard does the grinding.

Shouldn't man have a gizzard then? Not necessarily. Nature, in her wisdom, has given him a "gristmill" right at the entrance of the alimentary canal—sharp incisors in front to cut the food, and back of them molars or grinders to crush it as between an upper and nether millstone. Let these do their full work upon every morsel of food, mashing it to powder and half dissolving it in the saliva of the mouth, and the troubles below will cease—if only so much be swallowed as the stomach can conveniently hold and work up. If the teeth be sore or defective, cut or mash every atom of food to the smallest possible fragments, while still on the plate. This course rigidly followed will lessen the physician's bills, will aid to prevent or cure dyspepsia, will save aches and pains in the stomach, in the bowels, and in the head, and will produce far more nutriment, strength and vigor, from the same amount of food.

CHILDREN'S EATING.

What is said above, applies with especial force to children. How often their evacuations are filled with undigested food, yet these lumps of apples, of potatoes, and other vegetables, etc., can not pass through the body without producing disturbance and pain all along the alimentary channel. No wonder they suffer so much "pain under the apron." No wonder they are so often sick, are so often puny, and that so many of them die with summer complaints. The writer's rule is this: Until children are old enough to understand the subject, or become habituated to masticate every item of food swallowed, care is taken to have their meat cut fine, the potatoes mashed on the plate, and other vegetables either cut or mashed. At breakfast and dinner they eat what others eat, if prepared as above. As they retire early, the last meal is a very light one, consisting of a small quantity of bread and milk, or mush and milk, or bread slightly buttered. Since we learned to adopt the above precaution in regard to preparation of food, and light suppers, they have scarcely been sick at all, they do not complain of pain, have had no howel complaints, Summer or Winter, they show no signs of "starvation," but are vigorous in body and mind beyond their years; and they sleep sweetly and soundly, very seldom waking from 7 P. M. to near or after 6 A. M. Any variation from uniform good health has been traced directly to failure in carrying out our rules. We firmly believe that if these rules were generally adopted and thoroughly practised out, nine-tenths of the pain, sickness, and deaths among children would be prevented.

How to Prepare Hominy.

R. Avery writes to the *American Agriculturist*: "As we are frequently inquired of at the table, how we treat hominy to make it so white and soft, I send you the process for publication. Take strong lye, put it over a brisk fire and when boiling, turn in sound white shelled corn as much as the lye will cover. Boil and stir briskly, until the bran is loose (from 1 to 3 minutes), hurry it into clean water and wash and rub it thoroughly, to remove all specks of bran. Soak it several hours, changing the water each hour: it will then look white and clean. As much may be lulled at a time as there is lye to cover, and after the lye is out, it can be spread and dried for use.—In boiling the hominy, par-boil for a short time, then put it in boiling water, and as you fill up, do it with boiling water. Cold water would set it and it would get no softer. Boil very moderately 8 or 10 hours without stirring, or it will burn. In preparing it for the table, put some in a frying

pan, and when warm mash with a potato masher. Season with salt and gravy or use in milk. In cold weather 19 out of 20 prefer it to the best potatoes."

A \$150 Doll.

If the value of an article should be computed from the amount of benefit derivable from it, the following calculation, originating with some unknown author, is not far out of the way, and is well worth considering by the parents of every little girl. It is unnecessary to say that the passion for dolls with girls, as that for a whip and a knife with boys, is universal. It can be gratified almost without expense; the materials may be found in every rag-bag. But we believe a few shillings may be well expended for something more attractive than the ordinary rag-baby. Let the child have as good an imitation of a 'real live baby' as can be found, and her interest in, and care for the precious treasure will be greatly increased. Here are the figures as set down by one who has tried the experiment:

The increased attractiveness of home to the child is worth during her entire girlhood at least.....	\$25.00
The relief to the busy and often feeble mother while the child is amused with the doll.....	25.00
The cultivation of a cheerful disposition.....	25.00
The development of the best affections.....	25.00
The knowledge of dress-making, millinery, etc., gained by dressing the doll.....	25.00
The motives to faithfulness in other duties, which may be inspired by judicious management.....	25.00
Total.....	\$150.00

Who will say that a single item in the above account is too high? Neither can it be justly asserted that such trifles as dolls for children are unworthy the grave attention of the *Agriculturist*. Whatever ministers to home comfort and improvement, is matter for study; and besides, in judging of the importance of what pertains to children, we should in part look through their eyes. What little girl does not conceive this subject to be one of the very highest possible moment? A MOTHER.

German Economy.

Some of the pleasantest pictures of rural life in Europe, are those drawn by Mr. Howitt. Particularly in Germany, does he find much to interest him. One thing which struck him quite forcibly, was the carefulness with which the country people save everything which can be turned to use. For instance, the roadside is not always set with forest trees for shade and ornament, but is planted with fruit trees, and these are protected and cultivated hardly less than those of the orchard and garden. Again, more pains are taken, than with us, in saving and drying all kinds of fruit for domestic use and for sale in market. Cows are not generally pastured in Summer, but are kept in sheds or small yards, where they are fed in various ways. Grass and clover, refuse fruits, vegetables and meal, etc., are carefully provided for this purpose. In some cases, the women and children go out with sickle and basket, to cut up and gather grass and weeds from the roadside; the boys go into the marshes and woods to gather tall grass and even to cut shrubbery, all for the useful cow. Yes, the useful cow; for not only is every drop of her milk saved and turned to account, but her other droppings are assiduously collected, and applied where most useful.

The tops of potatoes, refuse of hemp, and stalks of beans serve as bedding for the cow; and even the rough stalks of poppies, after the heads have been gathered for oil and seed, are converted into manure for the land. Children are often sent into the woods to collect baskets and bags of moss for cattle bedding, which afterward goes into manure. In the Autumn, the falling leaves by the roadside and everywhere are swept up and stacked for the same purpose. The cones of evergreens are gathered and dried for lighting fires. While the women are tending their poultry and their cows, the knitting needles keep constantly going. In short, the Germans seem to have reduced the scriptural precept to systematic practice: "Gather up the fragments, that nothing be lost." And this same frugality and industry, we are glad to see, prevails widely among the Germans who have chosen this country for their home. With such habits of living joined with virtue, they are sure to prosper.

A Good, Cheap, and Wholesome Dish.

A writer in an Eastern exchange, says: "My family breakfasted this morning, July 20, mainly on boiled wheat. Boiled wheat and milk. Boiled wheat and maple sugar. Not wheat flour, nor wheaten groats, nor cracked wheat, but whole grains of wheat, shelled from the best heads, the larger the better, and soaked in cold water two or three hours, and then boiled in the same water one or two hours, or until quite soft, and the water all absorbed. It should all be cooked while other culinary operations are going on, as it needs to boil or simmer on a slow fire for a good while, and care must be taken at the last that it does not burn. To prevent this, it may be finished off by placing the kettle in a pan of water. How easy for our soldiers to have a change in the bread and salt meat rations, if they may be allowed to glean a few wheat heads, and boil the grains in their camp kettles. How convenient would this little item of knowledge in domestic cooking be to the wife of many a farmer who would gladly get up an extra dish for the tired harvest hands! Try it. How many families are this day living on short allowance, right alongside of a wheat field, or with grain stack or barn near the house, because they can not get it ground, the mill being dried up or broken down, or occupied by 'the army,' or suffering a collapse, so that no grinding can be had."

Hints on Cooking.

Housekeepers' "Recipes"—A Suggestion.—Mrs. W. S. Miller, Dutchess Co., N. Y., suggests that in giving recipes, it is advisable to have only such materials as are found either in the house or in an ordinary country store, and that the idea of economy and health should be kept in view. [This would limit this department to a particular class.—The greater the variety the better, and then there will be something to suit all classes.]

Good Cheap Brown Bread.—Mrs. W. E. Thomas, of DeKalb Co., Ill., writes: "... I would be unwilling to 'keep house' without the *American Agriculturist*. We have been following its suggestions to 'use more corn meal in our cooking,' and among the variety of recipes tried for 'Brown Bread,' the following has come into constant use: Stir thoroughly together 2 teacupfuls of corn meal; 2 of rye meal (or the 'seconds' flour of wheat); 1 of fine flour; $\frac{3}{4}$ teacupful of molasses; $2\frac{1}{2}$ teacupfuls of sweet milk; 1 teaspoonful of salt, and 1 of soda; $\frac{1}{2}$ teaspoonful of ginger. Cook by steaming $3\frac{1}{2}$ hours steadily. It is pronounced by all, most excellent, either warm, or cold."

Mince Pies without Brandy.—Contributed to the *American Agriculturist*, by Maria Ray, Suffolk Co., N. Y. Take 9 lbs. of boiled beef, 2 lbs. suet, 6 lbs. raisins, 4 lbs. currants, 4 oz. cinnamon, 2 of allspice, 1 of cloves, 1 quart molasses, 7 lbs. of clean brown sugar boiled down in 2 gallons of sweet cider to half the bulk. Mix all well together and pour the boiling cider on it. Cover close until next day, when it will be fit to be made into pies. This will keep good for at least six months.

Potato Custard.—Contributed to the *American Agriculturist* by N. Anderson, Franklin Co., Pa.: 1 pint mashed potatoes, 2 cups sugar, 1 of butter or lard, 4 eggs, nutmeg, thin it with milk, and bake.

Crumpets.—Contributed to the *American Agriculturist*, by N. Anderson, Franklin Co., Pa.: 1 quart bread dough, 3 eggs, milk enough to make a batter; let it rise; bake in cakes on a griddle.

Opening Cemented Fruit Bottles.—Mrs. Lucy R. Tatum, New Castle Co., Del. Place the inverted bottles on a heated stove until the cement in the party pans is melted, lift the bottles from the pans, turn them right side up, and the softened cork can easily be removed with a cork screw, or even a stout fork.

Apple Butter.—"J. W. M.," asks some, Keystone State housekeeper to furnish the *American Agriculturist* with a recipe for making the genuine Pennsylvania Apple Butter. Here is the writer's method: Boil new cider down one half. Pare, cut, and core equal

quantities of sweet and sour apples. Put the sweet apples in a large kettle to soften a little first as they are hardest. Add enough boiled cider to cook it. After boiling half an hour, stirring often, put in the sour apples and more boiled cider with molasses enough to sweeten moderately. Boil until tender, stirring to prevent burning. Pack in firkins or stone pots for Winter use. (The molasses is not needed, we think, while it would injure the flavor for many people.—Ed.)

Brandy in Cooking.—Mr. W. W. Nelson, Kent Co., Del., alluding to our remarks on the use of brandy in cooking, on page 372, December *Agriculturist*, gives a ease in point—many such eases have occurred. A young man was reclaimed from apparent ruin by the efforts of the temperance society, and was getting along finely, until he partook of brandy mince pies at a friend's house. This brought back his old appetite, and he is now a perfect sot. "If I can not have mince pies without brandy, I will not have them at all."

Cleaning Pigs' Feet.—J. W. Humphreys, Washington Co., Pa. Put the feet in cold water to soak over night. With a moderately sharp knife, scrape all parts thoroughly until the skin is clean and white. Hold the lower ends in hot water for a minute or two, to part the dew-claws and hoofs which can then be twisted off with the hand. Singe in a clear flame and they are ready to boil for soups or head-cheese.

BOYS & GIRLS' COLUMNS.

The Editor with his Young Readers.

A HAPPY NEW-YEAR to you young friend! I mean you who are just now reading this line, and not some other girl or boy.—Who spoke first this time?—When I was a boy, and it begins to seem a great while ago, though not so long that I have forgotten in the least how girls and boys thought, and felt, and acted, and I still enjoy playing boy with the little ones at home, for it is about all the recreation I have in these busy times—but I was going to say, that when I was a boy in years, there was a great strife to see who should say "happy New-Year" first. Sometimes we laid awake until the clock struck twelve, and then bounded out of bed and ran to papa and mamma's room, and waked them up so as to get the start of every one else. Well, I don't see that boys and girls are much different now. They have more books and papers to read, and probably know more of the world at the same age, but they have boys' and girls' feelings just as we had many years ago, and just as boys and girls did a hundred, and a thousand, and five thousand years ago. I don't believe there were ever more than two persons, who did not have nearly the same feelings, hopes, anxieties, love of sport and pastime, that you have. (Who were these two persons, and why did they have no childish sports?)—But I was speaking of the haste to wish the "Happy New-Year," first. Do you never, in this haste, forget what the words mean? If you really desire papa and mamma to have the happy year you wish them, how much will you do, to make it so to them? Will you do anything? Suppose you begin just now, to see how much happiness you can give them for one whole day. Will you? [I was going to tell some of the ways in which boys and girls may make their parents happy, but I see John and Mary have skipped over the rest of this, and have gone to the puzzles and stories. So I will stop here simply, expressing the hope that they will soon come back and in their own hearts, answer the above questions.]

A CHILD'S DEFINITION.—A little Sunday school scholar, when asked to define *Chaos*, answered, that it was "a great pile of nothing, and nowhere to put it."—Another when asked to define *slander*, said it was "when nobody did nothing, and somebody went and told on't."

A little girl of three years, who was born away beyond the Mississippi, where no orchards were as yet planted, was brought on a visit to Ohio, where she saw an apple tree in full bloom, covered with a profusion of white blossoms—a most beautiful sight by the way. Lifting her fat little hands in an attitude of devotion, she exclaimed: "See God's great big bouquet."

A little boy whose mother had promised him a present, was saying his prayers preparatory to going to bed, but his mind was running on a horse, and he began as follows: "Our Father who art in Heaven—ma, wou you give me a horse—thy kingdom come—with a string to it?"

To rise early requires quickness of decision; it is one of those subjects that admit of no turning over.

A little girl, while rumaging a bureau-drawer, found her grandfather's eye glasses, and at once cried out: "Oh, mamma, ganpa has gone up to hebbin widout his specs."

"IT'S COLD."

Do you smile at the plight of this poor urchin? Is there any fun in having such cold fingers, and ears nearly frozen? The boy thinks not; he is crying with cold. "The great lubber!" exclaim the sturdy boys who have just come in from skating or riding down hill, with cheeks glowing, and eyes flashing, and the blood dancing merrily through their veins, clear to their fingers' ends. "Cry for the cold! when a fellow has such fat cushions on his cheeks, and a stout pair of legs to run with; that is too ridiculous, he ought to be laughed at," say you. True enough. If he were doing his best in fighting the storm, pushing boldly ahead, and were then unable to keep from suffering, we should pity him. He would deserve pity.

It is pretty easy to foresee what kind of a man such a boy will make. If he has not pluck enough to bear up bravely against a wintry day, he will make but poor headway in the fiercer battles of life, when he must meet cares, trials, and disappointments. Usually those are least deserving pity who seek it most. The boy or the man who struggles on with a stout heart, no matter what difficulties beset him, will always command sympathy and respect; half of life's battles are won by going straight into the strife with a bold front. Command of one's own powers is in itself alone a great victory.

A Brave Boy and a Narrow Escape.

One day while the writer was in a steamboat crossing the ferry from New-York to Brooklyn, the pilot rang the bell for the engine to stop. On looking out to see the cause, there appeared a small sail-boat, just ahead, managed by a single boy, apparently not more than fourteen or fifteen years old. The tide was running strongly, and the headway of the boat could not be immediately stopped, nor could the little fellow quickly change his course, and it appeared almost impossible to prevent a collision and the sinking of the small boat. Did the boy lose his wits from fright, whimper and cry, and give up all for lost? Not a bit of it. Standing erect at the helm and doing his best to guide his boat, he sung out to the pilot of the steamboat "clear the track, or I'll run you down!" Such was the dauntless spirit of the little fellow, that the passengers cheered him loudly, and more than a dozen stood ready to plunge in to his aid, had his craft been overset. Fortunately this did not happen, though he escaped by only a few feet, and passed safely on, leaving all who had witnessed the occurrence in enthusiastic admiration of his presence of mind and intrepidity.

Girls Skating—Hints to Beginners.

A few years since any girl venturing to appear on skates, would have been called a "tom-boy" and frowned upon by her sex generally. But, for once at least, fashion has introduced a sensible change, and girls may enjoy this healthful and exhilarating exercise. The writer has had the pleasure of accompanying and assisting many young ladies in their first attempts at the art, and has seen the

good effects of proper indulgence in the sport. It has brought roses to many pale cheeks, strengthened weak nerves, sharpened poor appetites, and given new vigor for school and for household labors. Written instructions for learning to skate are worth little. *Go upon the ice and try*, is the only rule by which to acquire the art. It is very well to lean on the arm of a friend, during the first few attempts, but the sooner you trust your own powers, the quicker you will become a good skater. A few suggestions for choosing a pair of skates may be of service. For beginners, the runner of the skate should be about a quarter of an inch thick and slightly grooved, with the bottom nearly or quite straight from the heel to the upward curve at the toe. "Rockers," or skates having the bottom curved from heel to toe, are excellent for skillful performers on the ice, but a novice using them is likely to do most of his skating with his feet in the air. Never buy a skate with a long fanciful curve in front; though they are ornamental, many serious accidents have been caused by the ends of such runners catching in some obstruction. The straps should be stout, and so arranged as to hold the skate very firmly to the foot. The wider the strap the better, as it will be less likely to hurt the foot.

We have seen skates arranged to be fastened by screws to the sole of the shoe without the use of straps, but they did not appear to be held with sufficient firmness for good skating. Keep the ends of the straps well tucked away where they will not slip and get under the runner and thus give you a fall. See that the wood of the skate is strong, without cracks and checks, and that the runner is well fastened to it. Wear well-fitting but not tight shoes or boots of stout leather, and thick woolen stockings.

When warm with the exercise, do not stand still to 'cool off,' but move about more slowly, and after skating, always walk briskly home, to keep up active circulation of the blood, and prevent taking cold. Stiffness of muscles and lameness after skating may be prevented by thoroughly rubbing the limbs with a coarse towel or the hand, and putting on dry clothing if the garments are damp with perspiration. This should be done in a warm room, to avoid a chill. Do not make a business of this or any other recreation, sport, however innocent, to the neglect of home or school duties, but use it as a rest from them and a preparation for their more successful performance.

How to Save Your Shoe Leather.

Riding down hill on a sleigh is a fine winter sport. It makes the writer feel young again to think of the splendid times he used to have at it, when a boy. But he well remembers also that the fun was terribly destructive of shoe-leather. It was necessary to use the feet for rudders, and even stout cow-hide boots were soon whipped out at the toes. In the engraving below is shown an easily made apparatus for steering a sled, by which the feet are left at liberty, and the waste of leather prevented.

It is simply two stout oaken sticks shod with iron at the lower end, bolted one on each side of the sled. The hole for the bolt should be large enough to allow the sticks to move freely. By pulling on the upper end of the stick

the lower part is brought against the snow or ice, and acts as a rudder to turn the sled toward the side on which the stick is used. This will guide the sled more certainly than the heel or toe of the foot, and enable the rider to sit in an easier position, in addition to saving the shoes

The Statesman and the Horse.

Edmund Burke, one of England's greatest Statesmen, retired from London to spend his last days on his farm. While there, a report was started that he had gone crazy, that he went round his premises kissing the horses and cows. A friend immediately visited him to learn whether the report were true. He soon found that Mr. Burke had lost none of his mental faculties, and in a private interview with Mrs. Burke, he learned how the rumor of his insanity had been started.

Mr. Burke's only child, a young man of rare promise, had died a little while before, leaving behind him a favorite old horse. This animal, so endeared to him by association with his son, was turned into the field by Mr. Burke, with directions to all the servants that he should be treated as a privileged favorite. One day as he was taking his morning walk, the great man saw the animal at a distance, and noticed that he was recognized by him. The horse drew nearer and nearer to Mr. Burke, stopped, eyed him with a most pleading look of recognition which said as plainly as words could have done, "I have lost him too," and then the poor dumb beast deliberately laid his head upon Mr. Burke's bosom! Struck by the singularity of the occurrence, moved by the recollection of his son for whom he had never ceased to mourn, and overwhelmed with the tenderness of the animal, the illustrious Statesman clasped his arms around the neck of his son's favorite animal, lifted up that voice that had filled the House of Parliament with the noblest strains of eloquence, and wept aloud. It was not weakness of mind, but strength of affection, that bowed the man who had through life stood unmoved amid the fiercest storms of political strife.

LEARNED IT TOO LATE.—"Buy one of these superior razor strops Sir, and I will tell you a secret worth double the cost for only twenty-five cents." "I'll take one," said a bystander. Mr. Smith handed him a strop and a box of paste, and went on selling. "Look here," interrupted the purchaser, "you promised to tell me something worth double the price." "Ah, so I did," said Smith, "and it is this. If you had bought a box of the paste for five cents and put it on to your old strop, it would have made it just exactly as good as a new one."

EDITOR'S NOTES.—Being much occupied with business, I have left one of my associates to prepare this page, and must put in a word or two here, by way of query. First.—Is not that a poor boy in the picture, without clothes enough, or mittens, to keep him warm, and therefore to be pitied? Second.—Was that boy in the boat brave or reckless? Third.—Are there not other out-door sports quite as healthful, and appropriate for girls as skating? We do not say there are, for by all means girls should skate rather than grow puny in a hot room.—The skating and sliding down hill we can not write about from experience. Like thousands of our young readers at the West, we lived in a new, nearly level country without hills or ice ponds, and there were too many "chores" for us boys, out of school hours, to admit of skating or coasting. The work did not hurt us, but we are glad to see the boys and girls play—if they do not shirk all the work off upon their already overtasked parents.—O. J.]

The person who received an injury from an accidental discharge of his duty, is in a fair way to recover again.

A Boy that will Never be a Man.

In New-York, as elsewhere, it is becoming quite customary to send home articles purchased at the stores; some "stuck up" people have even ordered a spool of thread sent home. Happening into a book store this morning, we saw a lady purchasing some books for her son who was with her—for Christmas presents probably. When put up they made a package about ten inches long, five inches high, and six wide. She ordered them sent to her residence about $3\frac{1}{2}$ miles up town. The bookseller said to her boy: "Can't you take them up in the cars with you, my man? My porter is sick to-day, and it is quite inconvenient for me to send them so far home." "No! I don't carry bundles for a living."—We pitied that boy from our heart, and could not but feel that his mother was spoiling him by indulging him in such notions. Here was a boy 13 or 14 years old, who could not, or rather would not, carry a bundle of books for himself, that was not at all bulky, and weighed, perhaps, only five or six pounds. He was above "carrying bundles"—rather he was *below* it. He had not dignity or independence enough to be seen with a bundle, though it was for himself. He probably does not read the *American Agriculturist*, and so we can not speak to him directly, but to other boys we say, that if that boy lives to be forty years old, he will never be a man, in the true sense of that word. His parents may leave him money enough to keep him along awhile, but he will never earn or save much. He is coming up with habits that will unfit him for the real work which all successful men must go through with, no matter what their calling or business.—Two good illustrations are given in the life of Girard of Philadelphia, who rose from poverty to great wealth. While in a provision store, a man came in and bought a fish. Instead of carrying the fish himself, he offered a clerk a shilling to hire some one to carry the fish a few blocks. Girard at once offered to do it, and actually went by his side, carrying the fish, and received the shilling. You may guess the man's surprise when he afterwards learned who had carried his fish. Girard owned the entire block in which this man hired a dwelling.—At another time, two young men commenced the sail making business. They bought a lot of canvas from Girard, on credit, a friend having agreed to endorse their note. They each took up a roll to carry off, when Girard remarked: "Had you not better get a cart?" "Oh, no," they responded. "It is not far, and we can carry it ourselves."—"All right," said Girard, "but you may tell your friend he need not trouble himself to endorse your note. It's good enough without!" He well knew that men not above their business, not ashamed to do any honorable act, were the very men to succeed.

Answers to Puzzles and Problems in December No. (page 373). *Rebus.* No. 20. Key puzzle age 1 hoe awl bed ark: or by dividing the words a little differently, Keep up courage though all be dark.

Arithmetical Problem.—No. 22.—Paper money is at 24 8-33 per cent discount, reckoning gold coin at par.

Arithmetical Problem.—No. 23.—A. should have 80 cents, B., 20 cents of the dollar paid by C. for his share.

Riddle.—No. 21.—The engraving below is the answer to the riddle given last month, which reads: "A four handed rider, on a two legged steed, Whipped up the feathers and made very good speed."

No. 19.—Correctly answered by "R. G. F.", L. Lawrence Fisher, C. A. Veatch. No. 20, by George M. Kelly, "Random," Oren Stone, Mary Esther Parkin, Frank B. Conger, T. B. Cunningham, Jno. D. Talbot (and 21),

Wm. H. Tracy (and 23), Melissa Church, Jarvis H. Arnold, Walter E. Talmage, Lizzie Melcher, Arthur Gilbert, A. Martin. Rufus W. Weeks answers all. Isaac T. McLain, 22, 23; "C. C. C." 21; J. G. Bunnell, 22, 23, Cornelius Hoagland, Jr. 23; Frederic A. Fild, 23; A. G. I. C. White, 20, 22, 23; E. M. Swan, 20; B. F. Nye, 22.

New Puzzles to be Answered.

Fig. 1.

Fig. 2.

No. 24 and No. 25. *Two Picture Puzzles to be guessed.* How does Fig. 1 represent an economical man? How does Fig. 2 represent an enterprising business firm; and can you tell how it also represents a fortress?

No. 26—Riddle.

I have no head, yet from my lips
Fall words of wondrous weight;
I mark the course of mighty ships,
And guide affairs of state.
Darkness pursues my winding track,
Yet nothing gives more light:
You'll find me when you answer back,
If this you read aright.

No. 27. *New Rebus* containing a truthful sentiment. This is one of the most difficult puzzles of the kind we have published, and it will require no little perseverance to find the correct answer.

To Sunday-School Teachers and Others.

The new Question Book referred to last month, is now issued, and is even better than we expected. The binding is superior to what was intended at first, the covers being stiff, and in the usual style of binding such books, instead of in simple paper covers, as first announced. (This increases the postage to 4 cents, as it weighs over 3 oz.) After the sheets were struck off, we concluded to issue an edition at the Office of the *American Agriculturist*, where it will be supplied to all desiring it, by the single copy or by the hundred, at the uniform price of 10 cents, or 14 cents by mail—which, at the present price of paper, will hardly pay expenses. A hundred put up to go by Express or otherwise, will weigh about 20 lbs. The book is thoroughly evangelical, but not at all sectarian. It is simple, yet comprehensive; 52 lessons, including the leading events in Christ's life, and in the introduction of the Gospel afterward, are arranged in the order of time. Each lesson is completed on two pages opening together. The scripture text of the lesson is printed in full, with the probable time and place of occurrence. A condensed history of the events between each two consecutive lessons is given, so that by reading the lessons, and the connecting history, one gets an outline of all the events of the Gospels and the Acts, in order of occurrence. Simple questions directly upon the lesson are given in larger type. With these are a considerable number of other interesting and instructive questions, having the answer printed in full, or more frequently with the answer indicated by reference to a passage of scripture which gives a full explanation. Many interesting items of information, not accessible to the common reader, are given, as will be seen on looking over the questions. The book is specially valuable to the great mass of teachers who have not access to commentaries and other helps. The pronunciation of the more difficult proper names, is indicated by an *accent mark*. We are perhaps the more partial to the book, as it is the carrying out of a plan of systematic lessons we have long been aiming at; the ex-

ecution of the plan was intrusted to abler hands. Mr. Beach, Editor of the *N. Y. Sun*, a life long friend of Sunday Schools and for years Superintendent of one of the largest and best schools in the country, who chanced to fall in with one of the first copies, said in the *Daily Sun* of December 16:

"The Sunday Schools of the whole country have suffered from the want of a question book suited to their requirements, more than from any other single cause. Every thinking person has remarked it, and hundreds of authors have made vain efforts to fill the need. In the little book before us, the practical work of a practical man, practically engaged in the Sunday School work, we for the first time discover something really valuable. It epitomizes the whole New Testament history in chronological order, and is both text and commentary, teaching the teacher and helping the scholar. That it will be widely adopted in Sunday Schools we do not question."

The Two Caterpillars.

"Patches and patches, I'm sick of patches!" exclaimed George Rider, as he sat watching his mother, who was repairing the knees of his old pantaloons.

"Mother," he continued, suddenly, as a new idea started, "why did God make us poor? I'm as good as Joe Berry, but his father's rich, and he don't have to wear patched clothes. And you ought to see what nice things he has for dinner every day—pies, and cakes, and candy—and he's just as stingy as he can be."

"Poor soul!" said his mother, in a way that made George open his eyes wide.

"Why, mother, what do you mean?"

"I was thinking about two caterpillars," she replied.

"What a funny mother you are!" said George; "what in the world have caterpillars got to do with Joe Berry?"

"I'll tell you the story, my son," said Mrs. Rider, "and you may then answer your own question."

"Two caterpillars lived in a large garden; they looked very much alike, only one was covered with brown hair, and had black rings around his body, and the other had black hair all over, without any rings. The brown caterpillar lived on a large cabbage. It was a real palace for him. There were the large spreading leaves, over which he walked with as much satisfaction as ever a lord surveyed his extensive parks. He had fine rooms among the openings of the leaves, where he could curl himself up for a nap, snugly sheltered from rain and dew. Right at the top of the cabbage was his dining-hall, filled with the tenderest, choicest morsels of crisp leaves, which caterpillars love so well. Oh! he was very rich, and had everything a caterpillar could wish for. The little ants that climbed up to his palace, and the humble insects that picked up their living along the lanes and streets of the leaves, all looked up to him with awe, and saluted him very humbly as he walked about his wide domain.

"The black caterpillar had his home on a humble burdock that grew in a corner not far from the great cabbage. It was only a small plant, for if it had spread itself like the cabbage, the gardener would have quickly rooted it out. This poor fellow had to work hard for his living, and often to go hungry, for there were but few tender sprouts for him to nip, and he had to roam about and pick up here and there a bite as he could find it."

"But why didn't he go to the big cabbage?" asked George, who was becoming much interested.

"He would have done so," said his mother, "but the gardener had placed a bright piece of tin around the stem of the plant to keep off the worms, not knowing that one had already taken up his quarters there. The tin was so smooth that, though the poor caterpillar walked round and round it, he could not crawl half his length upward, before back he would fall in the dust.

"One day, while he was looking wishfully up to the luscious leaves above him, his rich neighbor happened to peep over the edge, and the poor caterpillar eagerly exclaimed: 'Brother!'

"'Brother, indeed!' muttered the other, proudly curling himself, so as to display his rings; 'you've made a mistake, I'm thinking.'

"'I'm thinking so too,' replied the poor caterpillar. He had intended to ask his neighbor to nip off a leaf from the cabbage and drop it down to him, but he saw it was of no use, so he crawled sadly back to his humble quarters on the burdock, and continued to grub for his living.

"The Summer passed on; the brown lordling revelled at his full table until he grew as fat as a prize-pig, but the heart of the cabbage was spoiled by his greedy tooth. The humble black laborer worked so faithfully at his burdock that it grew but little, and so the garden was kept free from its seeds, which would otherwise have ripened and scattered.

"And now the Summer was nearly ended, and the caterpillars knew they must prepare for the winter's cold.

"They therefore each left off eating, as is the custom of such creatures, and sought a secure place where they could rest in safety. The brown caterpillar climbed a tree at some distance from the garden, and spun for him-

self a magnificent hammock, which he hung from a stout branch. He was so fat that he had plenty of materials and he made his resting-place of three-fold thickness.

"His poor neighbor sought the shelter of a neighboring currant bush, and from his scanty store of silk wove a plain nest that would just hold his emaciated body. And so they both slept through the long Winter.

"When the time was come, the Master of Life sent forth his angels to waken the earth. And they poured out the golden music of light until it filled the deepest woods, and the flowers lifted their heads, and the air trembled with the hum of glad insects. The humble tenant of the lowly bush heard the joyous sound, and struggled forth from his hiding-place; how changed! He was clothed in purple and gold, and a shining crown was upon his head, and while he yet wondered, a bright troop of winged beings called him to mount to the upper air, and spreading his new-found wings, he soared away to bask in the full noonday.

"But alas for the poor, rich caterpillar! His silken robes held him fast; he could not break the strong bonds he had woven for himself, and there he must be a prisoner forever. And now would my boy be rich?"

"Yes, mother," said George, softly, "when God's spring-time comes."

Grammar Out West.

A Kansas correspondent "T. H.," writes to the *American Agriculturist*. "Will you please point out the incorrectness of the following sentences, which are almost universally in use at the West. 'Please pass me those molasses.' 'Them's good molasses.' 'Did you make any molasses?' 'Yes, a few.' 'Have you got any molasses (to a storekeeper)?' 'Yes.' 'I want to see them.' The above phrases are so common and contagious that many of the Yankees have adopted the error. How is it with oats? In Chester Co., Penn., it is classed with wheat, corn, rye, etc., in the singular number; here it is used in the plural, with beans, peas, potatoes, and other things ending with s."—The error in the sentences, as our young grammarians will see, consists in using "molasses" as a plural noun. "That molasses," "some molasses," "I want to see it," would be the correct way of using the above examples. The word "oats" is a plural noun. The Chester Co., custom of making it singular, is incorrect. Wheat, corn, and rye, have only the singular form

Barnum Nearly Humbugged.

When Barnum was about to erect a new building on the site of "Iranistan," his former house, which had been destroyed by fire, he was desirous of giving it a new and classic name. A friend to whom he applied, suggested the compound Greek word "Neos-kome," which he translated as "New-home." The word had a pleasant sound; Barnum liked it, and was about having it engraved on stone to occupy a conspicuous place in the building; but having so often humbugged others, he was naturally a little suspicious of attempts to humbug himself. He therefore consulted one of the knowing editors of the *American Agriculturist*, as to the meaning of the word "Neoskome." He was informed that it was derived from "Neos," new, and "skome," a joke or jest, the nearest word to humbug which the Greeks possessed. Barnum concluded not to adopt that name.

DEAN SWIFT, in traveling, once called at a house. The lady of the mansion, rejoiced to have so great a guest, with much eagerness and flattery asked him what he would have for dinner. "Will you have an apple pie, or a gooseberry pie, sir, or a cherry pie, or a plum pie, or a pigeon pie, sir?"—"Any pie, madam, but a magpie," replied the Dean, in his usual dry sarcastic manner.

HADN'T HIS SHARE.—"Mr. Brown," said an assessor the other day, "how many cows do you own?"

"Why do you ask?" was the query.

"Because I wish to levy on them," was the rejoinder.

"Well, let me see," said Mr. B. abstractedly, "how many cows does the law allow me?"

"Two," replied the constable.

"Two?" said Mr. B. with good-natured astonishment; "well, if the law allows me two, I wish it would make haste and send the other along as I haven't but one!"

"I can not conceive, my dear, what's the matter with my watch; I think it must want cleaning," exclaimed an indulgent husband to his better half, the other day.—"Nn, pa," said his petted little daughter, "I know it don't want cleaning, because baby and I washed it in the basin, ever so long, this morning."

She who marries a man simply for a "good match," must not be surprised if he turn out a "Lucifer."

Muggins, seeing a dead dog in the ditch, stopped, and after gazing intently, said to his companion: "Another shipwreck."—"Where?"—"There lies a bark that is lost forever."—His companion growled and navigated on.

PREMIUM LIST,

For 1863---Volume XXII.

Good Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the *American Agriculturist*.

(Premiums open to all who Desire them.)

N. B.—Persons interested in the following Premiums, will please note them carefully this month, as they will not probably be published again in full. They will continue open, however, until further notice—perhaps through the year, but the continued rise in printing paper may compel us to withdraw the offers after a time.

Every subscriber is invited to renew his own subscription, and to solicit others to subscribe. But in all those who will take the trouble to collect and forward clubs of subscribers, we offer a remuneration in the form of first-rate articles, as named below. (The pay thus offered is much larger than we could give in cash, as we get these articles on extra good terms when for premiums.)

WE WISH IT DISTINCTLY UNDERSTOOD that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand things, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.

We make no distinction between new and old subscribers in giving these premiums, but it is expected that every canvasser will not only gather up the names of old subscribers, but also secure a large number of new names.

Every person collecting names for premiums, should send two copies of each list of names—one of them marked "For Premiums," and also with the name of the sender.

Every person collecting names for premiums, should send the names with the money as fast as obtained, so that the subscribers may begin to receive their papers; Two copies of each list of names should be sent—one of them marked at the top "For Premiums," and also with the name of the sender. The premium will be paid as soon as any club is made up—if duplicate lists are sent.

Any person who has commenced sending in names at 80c, and finally fails to get the higher number of names, can fall back upon the smaller number, by remitting the 20 cents extra on each of the smaller number of names required.

Clubs need not be all confined to one Post Office.

Table of Premiums for 1863.

Names of Premium Articles.	Price of Premiums.	Names at \$1 each.	Names at 80 cts. each.
1—Good Books—See terms below.....			
2—Best Family Clothes Wringer.....	\$7 50	18	37
3—Nonpareil Washing Machine.....	\$16 00	35	75

24—Steel-tooth Cultivator (best).....	\$7 00	24	55
25—Family Lard and Wine Press.....	\$7 00	24	55

DESCRIPTION OF THE PREMIUMS.

Premium No. 1—Good Books.

Any person sending 16 or more subscribers, may select from our book list, (page 376,) to the amount of 12½ cents for each name, at the club price of 80 cents, or to the amount of 3½ cents for each name, at \$1 each. Farmers' Clubs have frequently joined together and obtained a good library through these premiums. N. B.—The books will be delivered to the recipients, (by mail or express,) free of all cost. See also about prices of Books in Basket Note.

No. 2—Family Clothes-Wringer.

This is a first-rate household implement—a great saver of garments, and of hard work. With this machine set on the edge of the wash-tub, the garments are easily and rapidly passed between two India-rubber rollers, the water falling back into the tub, and the garments dropping into a basket, in a drier condition than they can be wrung by hand, and therefore more quickly dried on the line. A child can in a few minutes wring out a tubful of clothes. We have had one in constant use in our family for nearly three years, and it is still as good as new. The machine offered, No. 2, is just the thing for family use. It is provided with cogs to move the rollers together, so that it is not possible to tear garments, as is the case with cheaper wringers not provided with cogs. We present one of these No. 2 Wringers to any person procuring and forwarding 18 subscribers, at \$1 each, or 37 at the lowest club price, (80 cents each.)

Premium No. 3—Washing Machine.

The Nonpareil Washing Machine we have had in use in our family for nearly a year past, and it has not only driven out half-a-dozen placed there on trial, but has really given excellent satisfaction. It is the only machine, out of twenty we have tried, which the "help" cheerfully use without compulsion. It is a labor-saver and a clothes-saver—two important considerations. (See descriptive cut, and advertisement on page 31.) The clothes are put in, in quantity, and quickly washed by simply turning a crank. The balance-wheel adjusts the force required, so as to make the turning easy. Take it all in all, it is the best Washing Machine we know of, and is worthy of a place in every family. They are of three sizes; we select No. 2, as the best size for common family use. The price of No. 2 is \$16. This machine we will present to any one forwarding 35 subscribers at the regular price, (\$1 each,) or 75 subscribers at the lowest club price, (80 cents.) The machine can be sent to any point as freight, or by express, and will be forwarded, free of all expense, except the freight after leaving the city.

Premium No. 4—Sewing Machine.

90 Subscribers at \$1 each, (or 130 at 80 cents each,) will entitle the person sending them to Wheeler & Wilson's best \$45 Sewing Machine, (including Hemmer), new from the factory, and of the very best make. There is no better family machine than this made, as we have proved by nearly five years' use in our own family, in connection with other machines. We want no better. The terms on which it is offered above, will enable many families to secure one without direct outlay of money. The Premium Machines will be selected new at the manufactory, and will be forwarded, well boxed, with full directions for setting up and using, and with no expense, except for freight.

Premium No. 5—Sewing Machine.

69 Subscribers at \$1 each, (or 98 at 80 cents each,) will entitle the person procuring them to Wilcox & Gibbs' \$35 Sewing Machine, including a set of Hemmers. This is the best machine of its kind, (sewing with one thread,) and has several points superior to other machines. It is neat, well made, simple in its operation; and having tested one in our own family for more than two years, we think highly of it, and can recommend it to those who can not afford to buy the higher priced double-thread machines. Some of our neighbors think this machine ahead of all others. Premium 5 will be selected and sent the same as No. 4.

Premium No. 6—Barometer.

19 Subscribers at \$1 each, (or 44 at 80 cents each,) will entitle the person getting up the club to one of Kendall's Aneroid Barometers, (Price \$7 50.) This is a good, portable instrument, and valuable to every person as a weather guide, as well as for scientific purposes. See page 37, December No. It will save to the farmer and others many times its cost, as a weather-indicator. These instruments resemble a large watch, 5 inches in diameter, and 2 inches thick. Each one is in a neat leather case, and when sent to a distance, this is packed in cotton, in a wooden box 4½ by 8 inches, and can go anywhere, by express or otherwise, with perfect safety.

Premium No. 7—The Aquarius.

This is a capital instrument, valuable to have in every house. It is a portable hand force-pump, which any one can catch up at a moment's warning, and throw from a pail or other vessel a steady stream of water upon a fire in a house, or elsewhere. It is supplied with both a jet-pipe and a rose, or sprinkler, and can be used for washing windows, carriages, &c.; for sprinkling trees, plants, destroying insects, &c., &c. With it, it is easy to wash the second and third story windows, and to sprinkle water upon the roofs, while standing upon the ground. Such an apparatus will often enable a person to use a bucket or two of water as to extinguish a fire breaking out where it could not be reached with water dashed on from pails. It is supplied with suction and injection India-rubber pipes, and with air-chambers to keep up a constant stream. The weight is 8 lbs., and it can be sent anywhere as freight, or by express. (Price \$10.) We will present an Aquarius complete to any one sending us 22 subscribers at \$1 each, (or 47 at 80 cents each.)

Premium No. 8—Melodeon.

125 Subscribers at \$1 each, (or 237 at 80 cents each,) will entitle the person getting up the club to one of Geo. A. Prince & Co.'s \$75 Melodeons (5 octaves). These Melodeons are of very superior tone and finish. We have ourselves used one for three years past, and it has given the highest satisfaction, and is pronounced by all who have heard it, as one of the very best. The different priced instruments are of equally good tone—the price varying with the size and style of finish. The size, prices, etc., of these instruments can be learned particularly, by sending a stamp to Geo. A. Prince & Co., Buffalo, N. Y., for an illustrated descriptive catalogue. The instruments given as Premiums, will be sent new directly from the factory at Buffalo, ready boxed, and without expense to the recipient, except for freight. Schools and churches can readily combine their efforts and secure one of these instruments. This has been frequently done. See "N. B.," under Premium No. 10.

N. B.—Any higher or lower priced Melodeons will be given for other lists, in the same proportion. See table above.

Premium No. 10—Best Dictionary.

23 Subscribers at \$1 each, (or 48 at 80 cts. each,) will entitle the person getting up the club to a copy of the large Pictorial Unabridged Edition of Worcester's Dictionary, (Price \$7 50.) This now stands confessedly the most valuable Standard Dictionary published. It weighs nearly 10 lbs.; is 12 inches long, 10 inches wide, nearly 4 inches thick, and contains 1854 pages of 3 columns each, giving the spelling and pronunciation, with full explanations, of every word in the English Language, and as a source of general information on all subjects, stands next to the Cyclopaedia. The Dictionary can be called for at our Office, or be sent by Express or otherwise, to any part of the country.

Premiums Nos. 13 to 18—Back Volumes—A First-rate Library.

These premiums (13 to 18,) will enable any one to secure the previous excellent volumes of the *American Agriculturist*, as far back as Volume XVI. These will be sent post-paid, in clean, new numbers, each volume by itself, with index. The whole five can be taken together, or one or more copies of any particular volume be selected, as desired. They will be presented as in the table above, viz: For 20 Subscribers at \$1 each, (or 35 at 80 cents each,) we will present **six volumes**. For 16 Subscribers at \$1 each, (or 30 at 80 cents each,) we will present **five volumes**.—For 13 Subscribers at \$1 each, (or 25 at 80 cents each,) **four volumes**.—For 10 Subscribers at \$1 each, (or 20 at 80 cents each,) **three volumes**.—For 15 Subscribers at 80 cents each, **two volumes**.—For 10 Subscribers at 80 cents each, **one volume**.—Let every one be careful to name just *which* back volumes are desired.

Premium No. 19—Best File for Agriculturist.

Jacobs' Portfolio File, made just to fit the *Agriculturist*—the name gilded on. This is a leather cover or portfolio, so arranged that successive numbers of the paper can be inserted in a minute, and be properly preserved in book form for reading. When one volume is completed, the sheets can be removed and stitched, and a new volume inserted. A single cover will answer for a dozen successive volumes. It is the most complete file yet made. The price is \$1, and the postage 25 cents. We will forward it, post-paid, to any one sending *eleven* subscribers, at the lowest club price, (80 cents each.)

Premium No. 20—Paints.

20 Subscribers at 80 cents each, will entitle the person getting up the club to an assortment of *Winsor & Newton's Water Color Paints*—consisting of 12 colors, put up in a neat mahogany case, with brushes, etc. These Paints are imported from London, and are by all considered the best in the world. They are adapted to the finest work, or they will make a neat and appropriate present to any of our younger readers. They will be sent post-paid any where in the United States within 3000 miles.

Premium No. 21—Paints.

15 Subscribers at 80 cents each, will entitle the person getting up the club to an Assortment of *Osborne & Hodgkinson's Water Color Paints*, consisting of 24 colors or shades, put up in a neat case with brushes, cups, etc. These are of American manufacture, and though not so fine as the above, will answer for ordinary practice by children or beginners, and for common sketching. Sent same as No. 20.

Premiums Nos. 22 to 26.

We have not space left to describe these particularly, this month. The Cylinder Plow was described in this journal last year. It is undoubtedly a great improvement. The Eagle Plow is well known, and so is the Hay and Straw Cutter, and the Steel-toothed Cultivator, one of the most useful implements on the farm. The Lard and Wine Press is a very convenient household implement, for pressing out lard or tallow, the juice of grapes, currants, berries, &c. For the prices, and subscribers required, see the table above.

The condensed Tables, given above, present in concise form a summary of the transactions for a month past. These figures are laboriously prepared from a large mass of notes collected by us daily, in the markets and elsewhere. It is to be noted, however, that the past business month has been only 24 days, owing to the occurrence of Thanksgiving holiday, to there being one day less in November than in October, and to the fact that there were five Sabbaths in November, this year, the last two of which are included in the month ending to-day. Still, it will be seen that the receipts were 131,000 barrels of flour in excess of the previous month, equivalent to 655,000 bushels of wheat. The receipts of Wheat are very nearly the same, if we allow for the extra days last month. Corn, Rye, and Oats, have come in more freely. The sales of Breadstuffs have been considerably lessened, as shown in the second part of table 1. By reference to table 2, it will be seen that while the receipts (allowing for one day less) have been about the same as last year, the sales have fallen off materially. Inland navigation is now closed, and though the railroads will continue to bring forward considerable supplies during the Winter, the prices will depend much upon the amount of the supplies already here. These are not believed to be very large. During the past month there has been no exciting cause of activity in Breadstuffs, and the market has been very quiet. The variations in the value of Gold and foreign exchange, have had the most to do with changes in prices. As was shown in an editorial article in the *American Agriculturist* for November (page 328), a rise in the relative value of Gold and currency, produces a corresponding rise in Sterling exchange, in which case it is more advantageous to send abroad wheat than gold, and the export demand is consequently better. During the past four weeks gold has vibrated between \$128 and \$133, or a premium of 28 to 33 per cent, upon the standard paper currency, and the prices of Wheat and Wheat Flour, and Corn, have changed nearly in the same ratio. The financial policy to be adopted by Congress is not settled. On the one hand it is proposed to raise money for the expenses of Government and the war, by selling stocks at whatever price they will bring in the market. This would be a move towards returning to a specie basis. On the other hand it is proposed to increase the issue of currency. If the latter policy be adopted, and many financiers think it the only practicable mode of raising funds, the relative value of gold will be increased with the increase of paper issues, and the prices of farm products will rise correspondingly. Thus: should the premium on gold rise to 100 per cent, it would be just as cheap to send abroad Wheat at the price of \$3 per bushel, in currency, as to sell it at \$1.50 per bushel if gold were the par standard of valuation. As we showed in the article above referred to, farmers are directly benefited by this disturbance in the relative value of gold and paper currency, whatever may be the present or ultimate effect upon other classes and upon the country at large. If the currency be doubled, the prices of farm products go up accordingly. It is true that these prices are not on a gold basis, but if the double price be in a currency that is at par in paying of debts for land, or other liabilities, the increased nominal price is directly advantageous. The general

opinion is that further issues of currency will be made, and that the prices of breadstuffs will go up; and we find dealers disposed to hold on to their present stocks.... Rye has come in much less freely, while the transactions in stocks on hand have been much lighter than the previous month, and market prices average about 5 cents per bushel higher than at the date of our last report.... Barley has not been so largely dealt in; the fever heat of speculation has in a measure subsided, and prices have declined from \$1.45@1.60 to \$1.25@1.45 per bushel. Provisions have not been very active. Mess Pork has advanced fully \$1 per barrel. Live Hogs are coming forward, for packing at this point, more freely than ever before, the receipts for the past week being 53,778. This is caused by the unsettled condition of things at the Southwest, and by the scarcity of barrel-makers at the West. New-York city is just now the "Porkopolis" of the country.... Groceries, Rice, Tobacco, and Wool have been quiet, without material change in prices.... Hay, Hops, and Seeds have been in good demand. The present prices, and any changes since last month, are indicated in our table of Prices Current.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been abundantly supplied during the past month, the average being 5,342 per week. Prices fell off a little Nov. 25., advanced 3/4 c. Dec. 2nd, and 1/4 c. more Dec. 9th. At the last general market, Dec. 16th, prices again declined 1/2 c. There were 6,276 beeves on sale, some of them very fine. Prices ranged at 10c.@ 12 1/2 c. per lb. for the estimated weight of the four quarters, for Christmas or premium bullocks; 8 1/2 c.@ 9c. for prime animals; 7c.@ 8c. for common to medium; while the poor grades, some of them genuine "scallawags" went at 5 c.@ 6c. The average of all sales was about 7 1/2 c.

Veal Calves.—Receipts have averaged 430 per week. Fewer calves are sent to market now than at any other season of the year. They sell quickly, the best for 6c.@ 6 1/2 c. per lb. live weight; 5c.@ 5 1/2 c. for good and 3c.@ 4c. for bobs and coarse overgrown calves.

Sheep and Lambs.—Receipts, are falling off and prices gradually advancing. Average receipts 10,039 per week, with a demand exceeding the supply. Several thousand dressed sheep are sent in each week, which makes up in part for the deficiency of live stock. Quite a number of extra large fat sheep sent in for Christmas mutton brought \$15 to \$18 per head. Some of them weighed 240 lb. each. Good sheep at 100 lbs. are worth prices equivalent to 5 1/2 c. per lb. live weight and fair stock 5 1/4. Pelts are worth in quantity \$2.00@2.25 each.

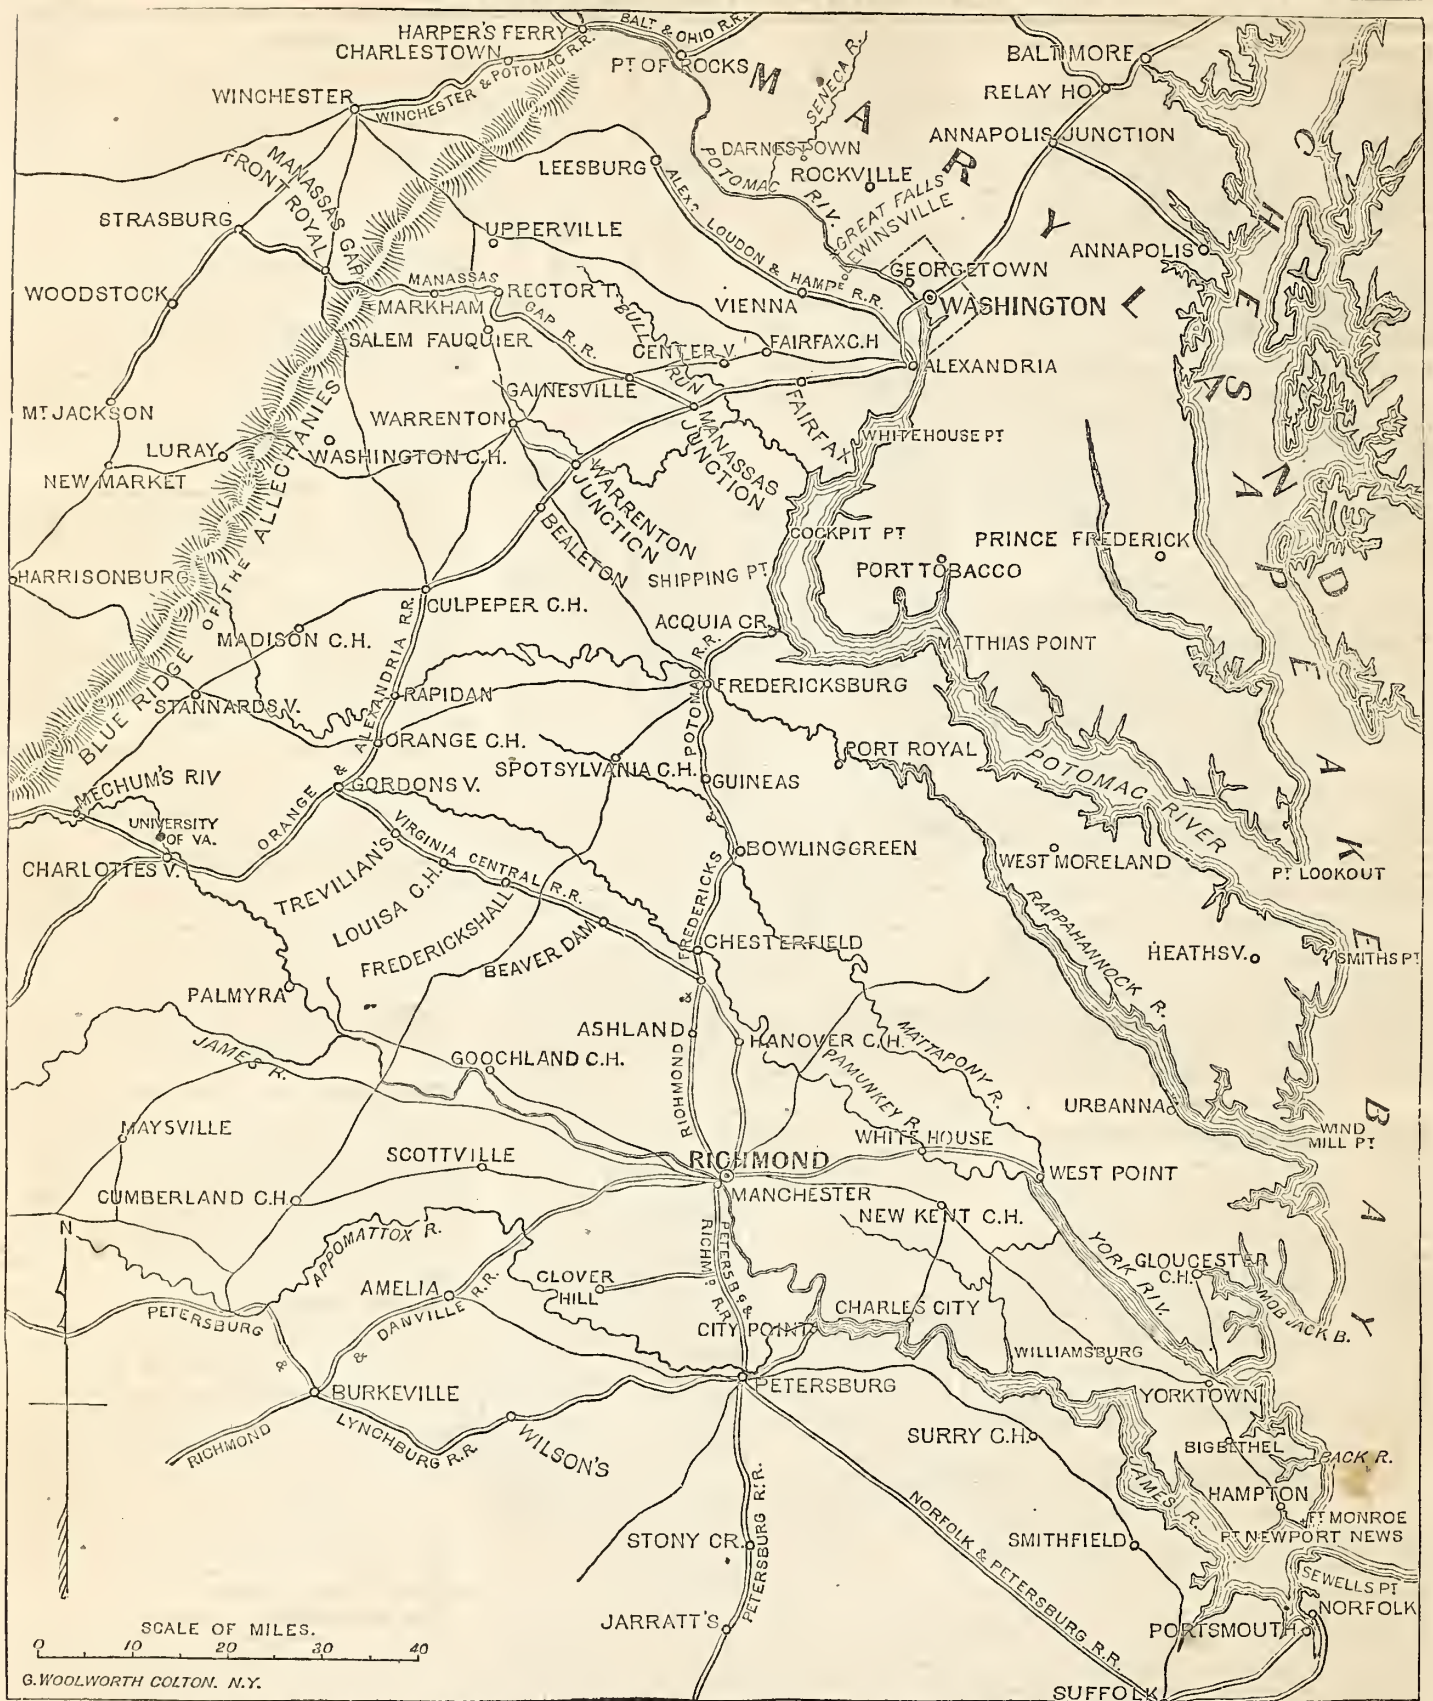

Live Hogs.—Were never before so abundant in this market. Receipts have averaged 47,166 per week, and numbered for the week, ending December 16, 53,778—the largest number ever received in a single week. In the face of such arrivals hogs are selling well and prices have advanced a little during the month. Prime fat, heavy, corn-fed hogs readily command 5c. @ 5 1/2 c. per lb. live weight; medium hogs 4 1/2 c.@ 5c., and distillery-fed 3 1/2 c.@ 4 1/2 c. Packing is carried on to an extent never before equaled in this region.

The Weather has generally been fine for winter with but little severe cold, the coldest day being 14° above zero. We have had comparatively but a light amount of rain and one fall of snow, an inch deep.—OUR DAILY NOTES CONDENSED, read: November 20, 21, heavy N. E. rain—22, cloudy, cool—23, 21, clear, windy—25, clear A. M., cloudy P. M., rain at night and on 26—27, 28, clear, fine—29, clear A. M., light rain P. M.—30, clear, mild.—December 1, light rain—2, clear, fine—3, cloudy A. M., and slight rain P. M.—4, cool—5, cloudy A. M., slight rain P. M., and 1 inch snow at night—6, clear, cool—7, coldest day of the season, mercury 14°—8, clear, cold—9 to 13, fine, clear, mild days—14 to 15, fog A. M., clear and mild P. M. both days—16, windy with showers—17, 18, 19, clear, cool.

The Rain Fall and melted snow, for month ending Dec. 15, amounts to 4.03 inches which fell sufficiently to be measured at six different times, besides other light showers. The Barometer has shown marked and extreme variations, the range being nearly 1 1/2 inches, from 29.35 inches to the unusual height of 30.70 inches on Nov. 16.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit).—r indicates rain—s, snow.]

Outline Map of Eastern Virginia.

The above map is inserted for the convenience of our readers, who are all doubtless interested in the momentous events now transpiring, and about to transpire in the region indicated.—A very large and very minute map of the whole of the State of Virginia, giving even the smallest towns, roads, etc., can be supplied at the *Agriculturist* Office for 25 cents. (Sent post-paid by mail for the same price.) The large map can no longer be afforded as a premium.

Exhibition Tables at the Office of the American Agriculturist.

The following articles have been placed upon our tables since our report in the November *Agriculturist*.

FRUIT.—Apples.—Baldwin R. I. Greening, Vandevere, from M. J. Taylor, of Gloster, N. J.... Sweet-sour apples, from Ich.

Pope, of Enfield, Mass.... Gloria Mundi, from C. H. Lillenthal, of Yonkers, N. Y.... Maiden's Blush, from Wm. E. Stiles, of Flushing, L. I.... Hawthornden, Dutch Mignonne, from P. J. Ward, of Bloomfield, N. J.... Mellow Heart, from Mrs. D. Lawrence, of Mt. Pleasant, N. Y.... French Pippins, from F. C. Farley, of Milburne, N. J.... Sweet-sour Apples, from C. J. Minor, of Woodbury, Conn.... Baldwin, Hubbardston Nonsuch, Killam Hill, from Josh. T. Holt, Andover, Mass.... Hawthornden, Granny Winkle, from E. Williams, of West

Bloomfield, N. J.... R. I. Greening, from Edw. Brown, of Deer Park, L. I.... Union Apple from Greenwich, Conn.... Gloria Mundi, from P. F. Peek, of Yonkers, N. Y.... Sweet-sour Apple, from T. Wileox, of Bennington, Vt.... Iron Apples, from G. M. Usher, of Port Richmond, Staten Island.... Gloria Mundi, from West Farms, N. Y.... Gloria Mundi, from Robt. French, of Westfield, N. J.... Penn Winter Apples, from S. W. Noble, of Jenkinstown, Montgomery Co., Penn.... Collection of Apples, from P. H. Ashton, of Middletown,

Coan....Apples from J. M. Hurlbut, of N. Y....Newtown Pippins, from Benj. Clapp, of Wappinger's Falls, N. Y....Wine Apple, from Josh. N. Hurlbut, of Winsted, Conn....Varieties for name, from Solon Robinson, J. M. Knowlton, J. P. Veeder, and C. Fenton.

Pears.—Beurre Diep, Beurre Clairgeau, Belle de Bruxelles, Vicar of Winkfield, Duchesse d'Angouleme, Seedling from J. H. Gibson, of Keyport, N. J....Vicar of Winkfield, Winter Nelis, from J. W. Everts, Brooklyn, L. I....Virgalieu, from Dr. Trimble, of Newark, N. J....Beurre Clairgeau, W. H. Goldsmith, of Lyons Farm, N. J....Lawrence, Beurre d'Angou, Duchesse d'Angouleme, Oswego Beurre, Beurre Clairgeau, from Orange Judd, of Flushing, L. I....Beurre Bosc, from Ang. A. Leverich, of Brooklyn, L. I....Branch with ten pears (magnificent), from W. D. Voorhees, of Newark, N. J....Flemish Beauty, Beurre Bosc, from Underwood Farm, L. I....Swan's Orange, from Geo. O. Street, of Mt. Vernon, N. Y....Winter Pears, from Thomas Sprunt, gardener to J. D. Wolfe, of Westchester, N. Y....White Doyenne, from C. S. Rast, of Fulton, N. Y....Vicar of Winkfield, from Isaac N. Pierson, of Newark, N. J....Bicknell Pears, from T. M. Brewer, of Hingham, Mass....Catillac Pear, from F. C. Farley, of Milburne, N. J....Gray Doyenne, from Moses J. Taylor, of Closter, N. J....Catillac Pear, from R. Sterling, of Suspension Bridge, N. Y....Varieties for names, from J. H. Gibson, E. Williams, Solon Robinson, and Moses J. Taylor.

Other Fruits.—Charter Oak Grape, from G. A. Blood, of West Farms, N. Y....Muskingum Grape, from H. M. Dewey....Cluster Grape, from R. Richards, of Tremont, N. Y....Isabella Grape, (very fine) from S. W. Clarke, of Naples, N. Y....Variety of Grapes for name, from Dr. Ward....Osage Orange Fruit, from J. VanBrunt, of New Utrecht, L. I....Pear Quince, from Gen. E. R. V. Wright, of Forest Home, N. J....Pear Quince, from E. Williams, of West Bloomfield, N. J....Orange Quince, from Chas. F. Day, of Oak Valley, N. J....Pear Quince, (finest of the season) from "Ignoramus," of Bloomfield, N. J....Cranberries, from W. J. Spence, of Eden Vale, L. I....California Tomato, (weight 2 lbs. 7 ozs.) from Mrs. Key, of Port Lee, N. J....Belle de Fontenay Raspberry, from W. F. Heins, of Woodstock, N. Y....Jar of Brandy Peaches, "Late Heath Cling," from Isaac Pullen, of Hightstown, N. J.

FLOWERS.

Chrysanthemums, (fine collection) from Wm. F. Heins, of Woodstock, N. Y....Cut Dahlias, from C. S. Pell, of New-York Orphan Asylum....Cut Dahlias, from Orange Judd, of Flushing, L. I....Dahlias from Ferd. Schleuter, of Williamsburg, L. I....Pompon Chrysanthemums, (fine collection) from H. T. Haviland, of Brooklyn, L. I....Pompon Chrysanthemums, from Mr. Lyon, of Rossville, L. I.

VEGETABLES, SEEDS, ETC.

Potatoes.—Pink Eye Rusty Coat, Bulkley's Seedling, Cuzco, Garnet Chili, Snow Flake, from Wm. S. Carpenter, of Rye, N. Y....Early Samaritan, from Simeon Allen, of East Chatham, N. Y....Peach Blow, from A. McCotter, of Holbrook, L. I....Peach Blow, (fine) from James M. Prime, of Monmouth Co., N. J....Peach Blow, from Wm. Robinson, of Flatbush, L. I....Peach Blow, from D. O. Calkins, of Brooklyn, L. I....Prince Albert, (very fine), from Dr. J. M. Howe, of Passaic, N. J....Purple Chili, from H. D. Van Brunt, of Englewood, N. J....Peach Blow, Prince Albert, from E. J. Swards, Jr., of Port Chester, N. Y....Bulkley Seedlings, from F. Vail, of N. J....Wild Mexican, from G. M. Usher, of Port Richmond, S. I....Potatoes raised on the Highlands of New-Jersey.

Corn.—Red, Caragua, Yellow Canadian, Pop, Rice, Brazilian (smallest known), Two Hybrids, from W. F. Heins, of Woodstock, N. Y....Pop Corn, from J. M. Hurlbut, of N. Y....Belden, Imperial King Philip, Devereaux, Mammoth Eight-Rowed, Richard's Treat, from Wm. S. Carpenter, of Rye, N. Y....King Philip, (from seed distributed from *Am. Agriculturist* office) from "Subscriber," of Logan Co., Ill....North Carolina, from R. P. Tins, of Glen Cove, L. I....Amagant Corn, from Mr. Swain, of Bronxville, N. Y....White Flint (fine) from A. Hollingers, of West Hoboken, N. J....Red (fine), White (curious) from Mr. Hume, of White's Farm, N. J....White Flint, (13½ inches long), from Mr. Woodward, of Mortonville, N. J.

Other Vegetables, etc.—Striped Gourd, from John Kjekman, of Brooklyn, L. I....Mock Orange Gourd, from Henry W. Carey, Fourth-av., N. Y....Fancy Gourd, from T. C. DeMarcellin, of N. Y....White Egg Gourds, from J. B. Bryan, of Brooklyn, L. I....Egg Gourds, from Morris Strong, of Northampton, Mass....California Gourd, from Chas. F. Day, of Paramus, N. Y....Chinese Egg Plant Fruit, from A. P. Cnamings, of N. Y....Purple Egg Plant, from A. H. Winship, of Flatbush, L. I....Turban Squash, from Fritz Meyer, of No. 25 Second-av., N. Y....Cheese Pumpkin and Fancy Squashes, from C. S. Pell, of N. Y. Orphan Asylum....Yellow Peppers, (very fine), from L. Jacobs, Staten Island....Red Peppers, (fine), from O. Jones, of Lyons Farms, N. J....White Sugar Beet, (weight 20 lbs.) from J. VanBrunt, of New Utrecht, L. I....Turnip Beet, from Jas. Martin, of North Prospect, N. J....Curious Beet, (set for seed, had grew seven additional beets—all from original root) from J. McElwee, of Walker Valley, N. Y....Blood Beet, from A. McCotter, of Holbrook, L. I....Blood Beets, (very large), from Chas. Harriman, of Irvington, N. Y....White, and Early Horn Carrots, (very fine), from Jas. P. Fagan, Esq., Supt. Ward's Island, N. Y....Early Short Scarlet Carrot, from John Fleming, of Readington, N. J....Long Orange Carrots, from J. VanBrunt, of New Utrecht, L. I....Long Orange and Altringham Carrots, from Mr. Halsted, of Rye, N. Y....Horseradish, (5 lbs. weight) from J. Reeder, of Duck Island, N. J....Peas for name, from R. Calif, of East Smithfield, Penn....Kohl Rabi, (12 heads from one root), from Dr. Barker, of Brooklyn, L. I....Turnip grown around an iron wrench, from Wm. Ritchie, of Scotch Plains, N. J....California Radishes, (very fine), from Wm. Blair, of Haekensack, N. J....Vegetable bouquet, (imitation flowers cut out from beets, carrots, turnips, onions, etc.—very fanciful and ingenious), from B. Stephens, of Washington Market, N. Y....Cotton grown in Illinois, from Rev. J. A. Bent, of Holeyton, Washington Co., Ill....Sorghum Seed, from John Fleming, of Readington, N. J....Palm-tree (in pot) from Port Royal....Red Onions, from A. McCotter, Holbrook, L. I....White Turnip, from Elisha

Mott, of Glenwood, L. I....Aplos Tuberosa, from Maj. J. B. Hoffman, Indian Agent of Dakota Territory....Buckwheat, (350 seeds grown from one seed), from Andrew S. Nash, of Westport, Conn....Sugar Cane from New-Orleans, (large growth), from G. Jones, Esq., Times Office, N. Y....Cauliflower, (fine growth), from Richard R. Bennett, of Fort Hamilton, L. I....Mangel Wurzel, (fine), from Chas. Harriman, Irvington, N. Y....Jersey Grasses, from J. B. Compton, of Manietown, N. J.

MISCELLANEOUS.

• New Corn Husker and Clothes Wringer, from Haines & Pell, of 37 Courtlandt-st., N. Y....Rattlesnake Skin, (very large), from C. R. Tyler, of Bay City, Wis....Currant Wine, from E. J. Swards, Jr., of Portchester, N. Y....Sorghum Syrup, (fine), from John Fleming, of Readington, N. J.

Business Notices.

Eighty Cents a Line of space.

Lands—To All Wanting Farms.

Large and thriving settlement of Vineland, mild climate, 30 miles south of Philadelphia, by railroad; rich soil; fine crops; twenty acre tracts, at from \$15 to \$20 per acre; payable within four years. Good business openings; good society. Hundreds are settling and making improvements. Apply to CHAS. K. LANDIS, Postmaster, Vineland, Cumberland County, N. J. Letters answered. Papers, containing full information, sent free.

A Constant Exhibition.

The Tables at the Office of the *American Agriculturist* have constantly during the entire year novel and interesting FRUITS, FLOWERS, GRAINS, VEGETABLES, ROOTS, ETC., contributed by SUBSCRIBERS, NURSERYMEN, GARDENERS and others, and almost uniformly present a very attractive and instructive exhibition.

Our tables are spacious, and the Office large and airy, and the best care will be taken of the articles contributed.

The Postage on the Agriculturist is positively only Six Cents a Year.

The law expressly says that a Periodical issued at stated periods, and not weighing over 3 ounces avoirdupois, shall be charged one cent per number, and only half this sum if paid quarterly in advance. The paper for the *Agriculturist* is purposely manufactured so that it shall weigh a little less than three ounces when printed; the legal postage is therefore only six cents a year, if paid quarterly in advance.

Circulation of the Agriculturist.

Beyond all doubt or controversy, the circulation of the *American Agriculturist* to regular subscribers, is many thousands greater than that of any other Agricultural or Horticultural Journal in the World, no matter what its character, or time or place of issue. The publisher is ready at all times to substantiate this statement by comparing books.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month. TERMS—(invariably cash before insertion):

FOR THE ENGLISH EDITION ONLY.
Fifty cents per line of space for each insertion.
One whole column (145 lines), or more, \$60 per column.

Business Notices, Eighty cents per line of space.

FOR THE GERMAN EDITION ONLY.
Ten cents per line of space for each insertion.

Business Notices, twenty cents a line.

A THOROUGH FARMER WANTED. with his family, to live on and manage 150 acres. To an intelligent, experienced, and properly qualified person, the best compensation will be given, and a permanent homestead in a delightful and healthy sea-shore situation. Address for information, E. R. LAMBERT, Esq., Bridgeport, Conn.

Help Wanted.

A single man—American or Scotchman preferred—wanted to take charge of a farm. He must be a practical man of experience, industrious, and honest, able to read and write. Also a neat tidy woman who can cook, wash, make butter, &c. Address JOHN H. ROCHE, Mead's Basin, Passaic Co., N. J.

A FARM FOR SALE.

A first rate farm on the Genesee flats. In the town of Chili, Monroe Co., New-York, containing about 111 acres of land, 4 miles westerly from the center of the city of Rochester. There is a good farm house, two first rate barns with cellars under them, sheds, etc.

There is an apple orchard; also peach and pear orchard, in number about 3,500 trees, excellent fruit. There is also an acre of Lawton blackberries, also about 100 grape vines, and considerable quantities of raspberries, &c., &c. The farm is now in possession of Wm. Cronk.

For further particulars apply to DAVID S. BROWN, 10 Peek-slip, New-York.

If you want a Tile Machine that with 2 men and 3 horses you can make 1000 Tile per hour, address F. M. Mattice, Buffalo, N. Y., or J. W. Penfield, Willoughby, O., or F. M. Mattice & Son, Rome, N. Y.

NEW-YORK Agricultural Warehouse, AND SEED STORE,

The largest assortment of Agricultural and Horticultural Implements, Seeds, and Fertilizers. R. H. ALLEN & CO.

OUR "EXCELSIOR BURR STONE MILLS,"

AND

ANTI-FRICTION

HORSE POWERS,

Have taken the HIGHEST PREMIUMS WHEREVER EXHIBITED! NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS last year.

THE MILL may be driven by horse, water, or steam power, does its work equally as well as the best flat stone mills in milling establishments, and requires but one-half the power to do the same amount of work. They are made in the best manner, and will last thirty years, and cost nothing for repairs.

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT. more work than ANY OTHER POWER IN USE.

EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

MILL STONE DRESSING DIAMONDS, Set in Patent Protector and Guide.

For sale by JOHN DICKINSON, Patentee and Sole Manufacturer, 61 Nassau-st., New-York. ALSO Manufacturer of GLAZIER'S DIAMONDS.

KEYSTONE CORN STALK CUTTER AND GRINDER. Sold by GRIFFING, BROTHER & CO., No. 60 Courtlandt-st., New-York.

The Eureka Feed Cutter.

A CUTTER ADAPTED TO THE WANTS OF FARMERS.

This cutter has important improvements. It crushes and cuts the heaviest corn stalks, hay and straw with great rapidity, by hand or horse power. Knives are cylindrical with shear cut, and easily ground and kept in complete cutting order. It is well made, easily operated, simple, durable, and effective. Hundreds are in operation to the satisfaction of the owners. Send for a circular to DAVID HAYNES, Proprietor, or H. K. PARSONS, General Agent, Harrisburg, Pa. Sold in New-York by R. H. Allen & Co., John Vanderbilt, Jno. Mayher & Co.

Horse Powers, Hay Presses, Cider and Wine Presses, etc.

For sale at the lowest market price, by GRIFFING, BROTHER & CO., No. 60 Courtlandt-st., New-York.

INGERSOLL'S IMPROVED

HORSE AND HAND POWER

HAY AND COTTON PRESSES.

These machines have been tested in the most thorough manner throughout this and foreign countries to the number of over 1200.

The HORSE POWER is worked by either wheel or capstan, and in many respects possesses unequalled advantages. We invite those wanting such machines, to write for a catalogue containing full information, with cuts, prices, etc., or call and examine personally.

Orders promptly attended to, by addressing INGERSOLL & DOUGHERTY, Greenpoint, Kings Co., L. I.

CORN SHELLERS, HAY, STRAW, & STALK CUTTERS, VEGETABLE CUTTERS, etc.

Warranted to be the best in the market. Sold at wholesale and retail, by GRIFFING, BROTHER & CO., No. 60 Courtlandt-st., New-York.

The best Holiday Gift, and greatly, constantly, and permanently useful. Specially full in Definitions and Illustrations of military terms. Sold by all booksellers.

RAISE COTTON.

Buy TURNER'S COTTON PLANTER'S MANUAL, which is a Compilation of Facts from the Best Authorities on the Culture of Cotton, its Natural History, Chemical Analysis, Trade and Consumption, and embracing a History of Cotton and the Cotton Gin. Far sale by C. M. SAXTON, 25 Park Row, New-York.

GOOD MEN WANTED in ALL PARTS OF THE COUNTRY,

To sell the **HISTORY OF THE GREAT REBELLION**, Sold only by Canvassing Agents. The work is printed both in ENGLISH and GERMAN. Vol. I. now ready for delivery. Apply to N. C. MILLER, No. 25 Park-row, New-York.

HAS TAKEN THE FIRST PREMIUMS AT TWENTY-FIVE FAIRS.

It saved half the wood and time, and the sugar and syrup were of a purer quality altogether than I had ever made before. M. C. MORTON, Bennington, Vt.

The syrup and sugar were very beautiful in color. The syrup of the first run looked like the white of an egg, or the clear honey that young bees make. It takes less fuel than any other way of boiling I have seen. I like the Evaporator much better than I expected when I bought, and would not now be without it. LEVI HART, Putnamville, O.

There is found in Cook's Evaporator a new and valuable principle that our old plans do not possess. You can make better sugar, boil faster, and it takes less wood and fuel to boil the same amount of sap in this part than in any other I have seen. GEORGE CAMPBELL, West Westminster, Vt.

The two Evaporators give entire satisfaction. A. B. ARMSTRONG, Dorset, Vt.

I saved one third of the wood and boiled away sap one third faster, and made sugar worth 10 or 15 per cent more than with the same sized pans or kettles, set and used in the ordinary way. P. M. HENRY, North Bennington, Vermont, 1860.

Adapted to the Brick Arch.

OVER FOUR THOUSAND IN USE!

Those wishing to enter upon the manufacture of Maple Sugar and Syrup, if making money is their object should purchase

COOK'S SUGAR EVAPORATOR.

For these among other reasons:

It saves one half the wood. It produces a sugar which excels in beauty and sells readily at one fourth more than that made in the ordinary way. Thus the manufacturer in every thousand pounds of sugar clears the price of one of our large Pans. That this is not an exaggeration may be seen by the following testimonials from maple men:

An excellent contrivance for boiling down "sap."—*Annual Rural Register.*

A very intelligent farmer told us last spring, that Cook's Sugar Evaporator was the best thing for making maple sugar in, he had ever seen.—*Field Notes.*

Makes Sugar of unusual whiteness and purity.—*N. E. Farmer.*

Cook's Evaporator is the best of the new machines for maple.—*Country Gentleman.*

We, therefore, cordially commend the Evaporator.—*Com. Ag. Soc., Addison Co., Vt.*

I have never yet seen any thing equal to it in the manufacture of maple sugar and syrup. It takes comparatively but little fuel, and the product is of a much more beautiful color and richer flavor than when made by the old process. J. RICHARDS, Tecumseh, Michigan.

Designed more particularly to make sugar from the Sorghum, but equally well adapted to making it from the sap of the maple.—*Boston Post.*

We commend the Evaporator as one of the really valuable improvements of the day, it being to the Chinese cane what the cotton-gin is to cotton.—*Middlebury (Vt.) Register.*

Manufactured by

BLMYERS, BATES & DAY,

MANSFIELD, O.

SEND FOR PAMPHLETS FOR PRICE-LIST TESTIMONIALS, ETC.

How to get a Patent.

A 3-cent stamp secures a copy of the "INVENTOR'S GUIDE." Address FOWLER & WELLS, 308 Broadway, New-York.

The Cranberry and its Culture.

The Subscriber has issued a circular from the press, treating on the Cranberry and its Culture. Said Circular will give persons the proper information as to the commencement of the culture. He will take pleasure in forwarding them to all parts of the United States, to those sending stamp to pay postage. Persons wishing plants in large or small quantities, may receive them by express, for wet or dry soil. Address GEORGE A. BATES, Bellingham, Norfolk Co., Mass.

ONION CULTURE—Third (new) Edition.

This work comprises in 32 pages all the particulars for successful Onion Culture, from Selection of Seed to Marketing the Crop—being the practical directions given by seventeen experienced Onion Growers, residing in different parts of the country. Price 21 cents (or 7 stamps), sent post-paid. Address Publisher of *Agriculturist*.

"THE HUMAN FACE DIVINE." A new system of PHYSIOGNOMY. Eyes, Ears, Lips, Mouth, Head, Hair, Neck, Hands, Feet, Skin, with all "SIGNS OF CHARACTER," in

The Phenological Journal

AND LIFE ILLUSTRATED, FOR 1863, devoted to ETHNOLOGY, PHYSIOLOGY, PHRENOLOGY, PHYSIOGNOMY, PSYCHOLOGY, and to all that relates to the Intellectual, Social, Moral, and Spiritual Nature of Man. Ample illustrated, and adapted to the comprehension of all. Samples, 10 cents. New volume. Only \$1.00 a year. Address FOWLER & WELLS, 308 Broadway, New-York.

DEFECATES THOROUGHLY WITHOUT CHEMICAL AGENTS.

The evaporator accomplishes all I hoped. I had one introduced into our new Christian Colony, which is being settled in Travertine County, Mex. It was operated by a new hand who had never seen one used. The result was the production of the finest maple molasses and sugar I have ever seen. Rev. J. B. Walker, Sandusky City, O.

Remarkable yet scientific decreasing arrangement. Most perfectly graded and finest colored (maple) sugar I ever saw. Hon. J. M. MILLIKEN, Ohio State Board of Agriculture.

We manufactured with less than two thirds of our former expense, and the sugar worth two cents per pound more. N. B. GRANT, Clynock, N. Y.

Sent the Evaporator to Mr. Fay. Greatly pleased with it. It created quite a sensation among his neighbors, and its operation surprised all who saw it. SHERRY SHARPARD & Co., Buffalo, N. Y.

The maple sugar made last season in this section on one of said Evaporators was a superior article, well graded, bright colored, and most pleasant to the taste. O. COOK, Lima, Ind.

Sugar worth 20 per cent more than any other.

TEETH
UPON ALLEN'S SYSTEM
CAN BE OBTAINED AT

22 Bond-st., New-York.

By this method the TEETH, GUMS, ROOF, and RUGÆ of the MOUTH are all truthfully represented, reflecting those delicate tints, shades, and forms peculiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evinced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, which rejuvenates the waning cheek.

A descriptive pamphlet may be obtained by addressing DR. J. ALLEN & SON, as above.

A SPLENDID HOLIDAY PRESENT.—Mme. DEMOREST'S beautiful and useful \$5 running stitch Sewing Machine, awarded first premium at the N. Y. State Fair. Every lady should have one. 473 Broadway. Sent free of express charges when the \$5 is sent with the order.

\$150. BEST PIANOS. \$150.

J. P. HALE & CO. having removed to their new ware rooms

No. 478 BROADWAY,

are now prepared to offer the public a magnificent NEW SCALE, full

7 OCTAVE

ROSEWOOD PIANO,

containing all improvements known in this country or Europe. Over Strung Bass, French Grand Action, Harp pedal, Full Iron Frame, for

\$150 CASH.

Warranted for Five Years.

Rich moulding cases

\$175 TO \$200.

All warranted made of the best seasoned material, and to stand better than any sold for \$400 or \$500, by the old methods of manufacture. We invite the best judges to examine and try these new Instruments, and we stand ready at all times to test them with any others manufactured in this country. J. P. HALE & CO., 478 Broadway, New-York.

RUSSIA OR BASS MATS, SELECTED EXPRESSLY for hudding and tying, GUNNY BAGS, TWINES, HAY ROPES, &c., suitable for Nursery purposes, for sale in lots to suit, by D. W. MANWARING, Importer, 248 Front-st., New-York.

BRONZE TURKEYS.—A fine lot of Bronze Turkeys, bred from Stock equal to any in the country. For sale by LUCIUS JACKSON, New-Milford, Conn.

The NONPAREIL WASHING MACHINE

Has been in operation since April, 1861, and the severe and varied tests, to which it has been subjected, in country and city families and laundries, demonstrate that two-thirds the labor and time, and half the soap required in hand washing, are saved by its use, and no injury can possibly result to the most delicate fabric from its action. It is a squeezing machine, and it washes with equal effectiveness a cambric handkerchief, or a bed quilt.

The machine is carefully made of the best materials, and its strength and durability will be found in keeping with its extreme simplicity. There is nothing in its construction liable to get out of order; and no training is required to enable the least skillful person to work it satisfactorily. A girl twelve years old can operate it.

Three sizes of family machines are made, their capacity being about the bulk of five, eight, and twelve shirts respectively. Prices: No. 1, \$12; No. 2, \$16; No. 3, \$20.

Machines to go by Power are manufactured for the use of Hotels and Laundries.

Circulars, giving full descriptions, will be forwarded by OAKLEY & KEATING, 73 South-st., New-York.

See Agriculturist Premium No. 3.

HOUSEKEEPERS BUY THE BEST.

Ask your Grocer for Pyle's O. K. Soap, Pyle's Saleratus, and Pyle's Cream Tartar. These are the best in use. The Editors of nearly all the New-York papers, and intelligent persons generally, use them in their families. For sale by Grocers anywhere.

Paper Has Gone Up.

Yes, it has! Last Spring such paper as we use was urged upon us at \$9.75 per ream (of large double sheets,) and with any length of credit we might desire. Our most recent purchase was at \$23.85 per ream, for the same or similar paper—cash down! Paper has gone up!

Many Journals Have Gone Up.

A large number of the newspapers of the country have put up their subscription rates. This has been made necessary by the increased cost of paper, the taxes upon advertisements, and by the advance in things generally.

Some Have Gone Down.

A considerable number of papers in different parts of the country have been obliged to stop or to continue at a loss. The list of suspensions counts by hundreds already, and includes several Agricultural Journals.

We Go Neither Down Nor Up.

The *Agriculturist* is too strong to go down, and it will not go up in price. The standard rates for many years past, will be continued for 1863, viz: \$1 a year; clubs of six for \$5; clubs of ten or more, only 80 cents each.

One Reason Why.

Our aim has been, and is, to supply a first class journal, reliable and useful in its character, at a price within the reach of the masses of the people. To advance the price would partially defeat one great object of its publication.

Another Reason.

Before paper rose very high, we were fortunate enough to lay in a fair supply ahead. Though our expenses are greatly increased, yet with the above advantage secured, and by hard work, and close economy in all that will not affect the intrinsic value of the paper, we expect to go squarely through the year—or at least without any severe loss.

More Reasons.

But the strongest, and most numerous reasons, just now, are the multitudes of subscriptions coming in—both new and old. Twenty five per cent more names have been received, since September, than during the same period last year. Such generous patronage will do something toward meeting the increased expense of paper.

And Now

Our readers know just where and how we stand. The *Agriculturist* will go on with unabated vigor, and undiminished in value, and yet at no extra charge, notwithstanding the greatly increased cost of publication. Will it not be a pleasure, then, to all our readers to reciprocate and each aid in raising the subscription list to the highest possible point? The paper would doubtless be interesting and instructive to some friend or neighbor, if brought to his notice. A word from you will add his name to our list and the result be satisfactory, we trust, to all concerned. What say you friend?

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Bound Volumes and Back Numbers can be Supplied.

We have complete sets of Vols. 16, 17, 18, 19, 20, and 21, both unbound, and bound in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, 20, and 21, unbound.....\$1.00 each.
Volumes 16, 17, 18, 19, 20, and 21, bound.....\$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.

(They can not go unpaid.)

Volumes 16, 17, 18, 19, 20, or 21, unbound.....\$1.12 each.
Volumes 16, 17, 18, 19, 20, or 21, bound.....\$2.00 each.

BINDING.—Sets of numbers sent to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 12, to 21 inclusive, at 25 cents per cover. Covers can not go by mail.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH, alone worth the cost of the paper.

A full CALENDAR OF OPERATIONS every month. THREE TO FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors are all PRACTICAL WORKING MEN. The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE.

(For either the English or German Edition.)

One copy, one year.....\$1.00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents. Postage anywhere in the United States and Territories must be paid by the subscriber, and is only six cents a year, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

AMERICAN AGRICULTURIST,

VOLUME XXII—No. 2.

NEW-YORK, FEBRUARY, 1863.

NEW SERIES—No. 193.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

In England, where the influence of the surrounding sea water modifies the temperature of the atmosphere, plowing and even sowing of seed are frequently begun as early as February. Here, except at the far South, all field operations are suspended, though the continuance of such warm weather as has prevailed throughout the first half of the Winter season proper, would admit of plowing the lighter sandy soils, or all such as will not pack and bake if worked in a wet condition. Other field work, gathering stones and roots, draining, fence building, etc., could also be carried on with facility. But we can scarcely look for such weather in February. Maple sugar making, and cutting and hauling fuel, timber, and fencing materials, are the chief out-door employments, aside from the care of domestic animals, and the important work of increasing the manure heap as much as possible. This is the season for "manuring with brains," as our friend Tim Bunker would term it. Western farmers tell us they do not need so many chapters on farm manure; that they are about as much troubled to get rid of the stuff, as Eastern farmers are to procure it. But Tim Bunker's manure will certainly pay, even on their rich virgin soils. We can not too often enforce the fact, that "it is the mind that makes the man." It needs no argument to prove that of two farmers having equal health, equal physical strength, and placed in similar circumstances, the one having the most brains, the one who thinks most, and plans best, will achieve the greatest success, with the least wear and tear of muscle. Abundant examples in proof of this are to be found everywhere. We would impress upon farmers the fact that thinking and intelligence pay quite as well in soil culture, as in any other pursuit. Reading is an aid to thinking. That man is to be pitied who is so opin-

ionated, so self-sufficient, as to say in earnest, "I want none of your book farming." What is this "book farming" but the effort to collect the opinions and experiences of a great number of men, and convey them in printed, instead of spoken words. No one can read a sentence relating what some one else thinks of a particular crop or mode of culture, or describing another's practice, without being led into a new train of thought, and in the end his own practice will be improved thereby. Then, again, how much it lightens one's labors, how many weary hours of work pass away more pleasantly, if he have new subjects of thought to occupy the mind. How long the day is, when following the harrow, or swinging the ax from sunrise to sunset, if one have not a store of ideas to draw upon. Take as a single illustration, the article on page 52 of this number of the *Agriculturist*. Will it not relieve the tediousness of "sprouting potatoes" all day, to see in each tuber a beautiful arrangement of the stem and eyes? There are ten thousand such things to be observed and learned in connection with every department of farm life—more here than in any other business pursuit, because a greater variety of objects are constantly presented to the eye. Not only the trees and plants, but even the sticks and stones speak a language to him who learns to read that language. And this passing month of February is just the time to be reading, thinking, and planning; the time to be laying in a store of thoughts to be worked over in the mind next Summer while the hands and eyes are occupied with work. It may "please the flesh" to lazily while away the stormy days and the evening hours at the store, in trashy gossip, and in story telling; but the gathering of information from books and papers treating of field and garden crops, of animals, of improved implements, of the structure of soils and of plants, of the laws of vegetable growth, etc., will not only furnish food for thought while at hard labor, but will also lead to new plans that will put money in the purse.—As usual, we place together here sundry hints which are designed, in the main, to be merely suggestive.

Work for the Farm, Household, etc.

Animals.—Have the hints thrown out last month been acted upon? They will bear looking over again. A full grown horse, or working ox, or milch cow, may remain about stationary, if already in good flesh; but with these exceptions, every animal should be improving in condition from week to week. It is a mistake to suppose that animals must make their growth and lay on fat during the Summer, and merely be a bill of expense during Winter. If a calf, steer, heifer, sheep, or hog, be not plainly increasing in weight, there is some defect in the feeding, sheltering, watering, or salting, and the defect should be looked into and remedied at once.—The colt, calf, or lamb, to be dropped in

Spring, will be of greater value if the dam be well cared for now. It is well at this season to inquire whether the breeds of animals now kept, are the most profitable, and how improved blood may be introduced. If a colt from one stallion be worth \$20 more at birth than one from another, will it not pay to give \$10 more for the use of the former? The breeding and raising of a horse worth \$150 costs no more than for one worth only \$75 when grown. The same hints apply to other animals. "A word to the wise," etc.

Buildings.—For those already constructed, the directions of last month will nearly suffice. If the weather admit, painting may be done now, and during March or early in April; it is more lasting if dried and hardened during cool weather, than if applied when the sun shines brightly upon it. A coat of paint on weather beaten clapboards will add several years to their durability.—If new buildings are planned for, the sooner the lumber can be procured and set to seasoning, the better. Study convenience in the internal arrangement of dwellings. A slight change in the location of rooms and stairs may save hundreds of steps daily, for a life time. A cellar under the whole house costs only a little extra digging and two pieces of end or side walls, more than for half a cellar. A two-story house requires no more roofing and flooring, and but a little more siding up, and wall plastering, than does a story-and-a-half house.

Corn, in the crib, bin, or still in the sheek needs special care; it is one of the most difficult crops to keep in good condition, owing to the moisture in the cob and chit. A large amount of that brought to this market is sold as "unsound" at considerably less than the market price for sound corn. A very little extra care in the farm storage will often add ten to thirty per cent., or more, to the market value, which is all clear profit, as the cost of handling and transportation is not increased. There should be no dampness or heating in the crib, or wherever it is kept. Narrow cribs, with free ventilation, are essential. In preparing corn for market, it is advisable to break off the tips of the ears before shelling, and feed the small and imperfect kernels. These fill in the chinks in measuring, so as not to increase the bulk materially, and do not add their feeding worth to the weight, while the plump grain kept by itself, will sell more readily and for a higher price. Let seed corn for next year be selected from the largest, soundest ears, and be kept dry.

Corn Stalks, contain much more nutriment than is generally supposed, judging from the little care used to preserve them in good order. Cattle can not be blamed for refusing them when weather beaten by exposure to rains, and injured by heating in unprotected shocks. We know of an instance where a man kept a horse and cow all through Winter, from grass to grass, mainly on the stalks from 1½ acres of well

grown corn. The stalks were cut early, dried in small shocks, and then stored under dry covering. They were cut very fine, wet, and a little ground stuff sprinkled over. Less than half a ton of hay was used during the winter—a small bite daily. The animals kept in excellent flesh and the cow yielded a good flow of milk. Even in the dry state, corn stalks contain considerable saccharine matter which is a directly nourishing food.

Draining is always important. One half of all the farms in the country would be doubled in real value for cultivation, if freed from water, which shuts out air, keeps the soil cold, and by its expansion and contraction in freezing and thawing, tears and breaks the roots of winter crops. A single deep under-drain run through a field apparently dry, will show marked good effects upon the crops growing within twenty feet on either side. Draining may be attended to this month where the ground is not frozen, and often where only a few inches of the surface is hardened. Try one drain this Winter, if no more: it will speak in stronger language than we can write.

Grass Land, whether meadow or pasture, is injured by treading of cattle, especially when partly frozen, or in the soft state following thawing out. See "Basket" item on this subject, on another page.

Hogs.—The hints given last month are important, and no additions are needed this month.

Horses.—See notes last month, and under "animals" above. Good shoeing is important. There are plenty of blacksmiths, but very few skillful horse-shoers. There should be schools of instruction on horse-shoeing. An acquaintance of ours, bought a good family horse very cheaply because she appeared to be tender-footed, and was slightly troubled with the "heaves." He took her to another blacksmith who had skill enough to change the form of the shoe on the lame foot; and instead of using long dry hay, he cut and wet all her food. For a year past she has neither limped nor wheezed, and being just the horse wanted among a family of children, she is worth \$50, perhaps \$100, more than when purchased. It don't pay to employ a poor horse-shoer, because he works cheaply, and because his shop happens to be hard by.

Hired Help.—Now is the time to be looking after the summer laborers. To secure a good man, better take him a month earlier. It costs no more to board and care for a good hand, than a poor one. The cheapest man we ever employed cost us \$20 a month, he boarding at home on Sundays, while plenty of other men were to be had for \$10 or \$12 a month. A man that is "handy," that will set himself to work and keep himself and others at it, that will handle tools carefully and yet effectively, that will not injure the morals of your boys by profane or lewd talk, is cheaper at \$25 a month, than one of the contrary sort who will stay for his "board, lodging and washing."

Manure—Bones.—The collecting should go on vigorously this month. Stop that dark stream running from the yard; there is a good ear or two of corn in every pint of it. Read again the hints last month. **Bones** required for spring manure should be put to dissolving now. Take one or more wooden hooped tight casks—old meat barrels or molasses hogsheads will do, if tight—and set under cover, or shelter with a board. Put in say 8 gallons of water, then pour in, a little at a time to avoid great heat, $2\frac{1}{2}$ to 3 gallons of Sulphuric acid (oil of vitriol) which can be bought by the carboy, for $1\frac{1}{2}$ to 3 or 4 cents per pound, according to the distance from the manufactory. Then put in and punch down with a stick all the bones the fluid will cover, or even more. If the bones are closely packed, the fluid will rise to the top of the cask. Leave them to soak 5 to 8 weeks, stirring them well, and punching them down every three or four days, and adding fresh bones as there is room. After a few weeks the undissolved pieces may be taken out, and the fluid be mixed with a large quantity of muck or soil to dry it off. This will be a strong fertilizer—better and cheaper than

any thing to be bought in the market—if the bones and acid can be got at moderate expense. Keep a bucket of water and some weak lye or dissolved soda or potash, or thick lime water, standing near the cask, for instant use, should any of the strong acid chance to spatter upon the hands, feet or clothing.—Much valuable time will be saved in spring, if manure be hauled to distant fields now. If placed in small heaps, and covered with a few inches of muck or good surface soil, it will not be apt to fire-fang. The soil on it will shed off washing rains, and arrest escaping gases, and itself become quite a good fertilizer.

Maple Sugar.—For full directions, see article in this number, also in Vol. XXI, February No., p. 42.

Potatoes.—Those intended for seed should be kept cool in order to prevent their starting. Though those from which the sprouts have been rubbed will throw out others and grow, (see page 53,) yet there is no doubt that the first crop of sprouts will give the most vigorous plants. In some places the potatoes have rotted. If troubled in this way, procure seed from localities free from disease. Many farmers only plant one sort and that a late one. A few bushels of an early kind always meet with a ready sale, to say nothing of the luxury of having them upon the table in July. The seed can be looked after at this season.

Plowing may be done on light soils where the ground is open. A large Maryland farmer who visited us on January 15th, stated that his plows had hardly stopped up to that date. He turns over sod land, even when heavy soil and quite wet, and surface plows it in Spring when dry and warm. The sod keeps it open below, and plowing and harrowing in Spring pulverizes the surface for a seed bed. He says long experience has proved this plan to be advantageous.

Poultry.—The directions given in this department and elsewhere, last month, will be pretty certain to produce an abundance of eggs now. Eggs designed for hatching early chickens should never be chilled. As soon as laid, put them in a cool, dry place in the cellar, or elsewhere, so that they be not too warm or too cold. Handle carefully. New breeds are often introduced most cheaply by procuring eggs. We wonder why more persons do not provide and advertise eggs of the different improved breeds. Carefully packed in some soft elastic material, they can be safely sent by express or other conveyance.

Sheep.—The demand, at good prices, will continue large for wool, for mutton sheep, for spring lambs, and for growing sheep. The flock should have the best care and attention now. For sundry hints, see page 42.—Numerous complaints of dog depredations have been recently reported, even where the laws are good and strong. Stir up the public sentiment in favor of enforcing these laws. Shoot or poison every dog larger than a rat terrier that looks at your premises. The sheep already killed by dogs the present winter, are worth more than all the dogs on this continent. In view of the immense damage they have done to the sheep raising interest of our country, we heartily wish every dog could be treated as the Dutchman's dog was—had his "tail cut off short, close up behind his ears."

Tobacco.—If this is to be cultivated, the field it is to occupy, should be prepared by high manuring and deep working. A good loam, in a situation not liable to early frosts, is to be selected. Good barnyard manure at the rate of 25 to 50 loads to the acre should be plowed in deeply. As the planting will not take place until June, the work of preparing the soil may be done at any convenient time—the manure is to be looked after now. Tobacco makes a heavy draft upon the soil, and if cultivated year after year upon the same land, will inevitably ruin it. It should only be grown as part of a rotation. The culture will not be profitable in very windy localities, as the leaves are torn by high winds, and their value much diminished. The seeds are not sown until April, at which time seasonable directions will be given for the preparation of the bed. The kinds cultivated are the Connecticut

Seed Leaf, and the small leaved Cuba. The former is largely grown in the valley of the Connecticut, and elsewhere, and is especially valued for wrappers to cigars. The Cuba is used for filling cigars, making chewing tobacco, etc.

Tools.—See "Implements" last month. Now is the time to get them all in order, and to procure all new ones that will be needed next Spring. The best are the cheapest, without regard to prices. A good steel hoe, rake, plow, or other implement, will outlast several soft iron ones, and do their work better. As we have somewhere before illustrated, a man will cut as many cords of wood in a week with a first rate ax, as two men can cut with poor axes, while the cost of the two tools will barely vary 50 cents—hiring a week's extra work, to save 50 cents in the cost of an ax is not the best economy. The illustration holds good for all other implements—out-door and in-door as well.

Orchard and Nursery.

The directions for this month might all be condensed into "get ready for Spring work," as there are but few localities in which the season is far enough advanced to allow of much besides preparatory work. The hints and suggestions of last month apply mainly to this also. But a great deal of thinking and planning can be done now, to be executed at the proper time. Every little convenience prepared now, will save valuable time when the press of spring work is upon us.

Cions should be cut while there is abundant time to make a careful selection. Except when making experiments, do not graft an unknown sort merely because a neighbor says it is good. In grafting over an old orchard, select kinds which are known to succeed in your own neighborhood. Some of the finest fruits in one locality, do poorly in another place. Cut cions from trees which you know to be true to name, and label them so that there can be no confusion at grafting time. Select healthy, well ripened wood, cut when not frozen, and preserve in earth in the cellar.

Cleanse the rough and moss covered trunks and limbs of old trees by scraping; wash with strong soap suds or weak lye.

Fruit stored in the cellar or fruit room, should be looked over, and decaying specimens removed. Carry that required for the table to a warm room to ripen off a few days before it is needed.

Grafting.—Those who go about to do grafting, generally begin very early, in order to make their season as long as possible. Grafts put in long before the growing season commences, are exposed to drying winds, and are liable to accidents. Root grafting can be performed in the house, the grafts being kept in boxes of sand in the cellar until the time for planting out.

Insects.—Destroy the eggs wherever they can be discovered. They are often found glued to the twigs. Crush those in the cocoon or chrysalis state.

Manure.—A good top-dressing placed around the trunks, as far out as the roots extend, is of more benefit to the tree, than a quantity of manure piled around the trunk. Fruit trees should not be over manured. Make good use of ashes in orchard and nursery; pear trees are much benefited by them.

Orders.—If you failed to procure nursery stock in the Fall, attend to it at once. Nurserymen generally fill those orders first which are received first, and those who send late fare the worst. Look over the catalogues carefully, and have a full understanding as to the size and quality. Better pay a large price to a good, well-known, honest nurseryman, than to take as a gift, the trees of those who will fill your order any way—with some kind of trees, if they have not an abundance of what you want. Some of the nursery stock advertised at very low rates, is the most costly that can be bought.

Pruning.—Winter pruning is generally abandoned by good orchardists. The wounds made now are exposed to the weather, and do not heal over as readily as when it is done in early summer.

Planting should be done as early as the weather will admit. Have the ground well prepared, and don't hurry the job. Recollect that an orchard is for a life time, and extra care in planting is time and labor well invested. Stake the trees, to prevent them from being whipped about by the wind.

Stakes, labels, tallies, mats for packing, etc. See that these are ready and in abundance. Labels and tallies can be made at odd hours; have the latter strung and ready for use.

Kitchen and Fruit Garden.

Here, too, but little can be done except in preparing for the season of work. Where *forcing* is carried on, this is a busy month, but the number who grow vegetables in this way, is limited to a few professional gardeners who do not need our suggestions. The demand for early vegetables, which in England is supplied from forcing houses, is here satisfied by the products of more Southern localities, the West Indies and other Islands, and the Atlantic coast of the United States.

Cold Frames, need the same care as directed for last month—plenty of air on mild days, and protection from sudden changes of temperature.

Cuttings of gooseberries and currants may still be made: prepare them for planting, by carefully cutting out all the eyes from the portion which is to go below ground. Bury them in the cellar or open ground, if it is not frozen.

Grape Vines, should have been pruned in the Fall. Those neglected then, should be trimmed as early as possible now.

Fences.—Repair and make proof against stray animals. See that the gates have fastenings and will swing without dragging. A few nails driven in time will often prevent much trouble.

Hot-beds for the family garden had better be left till next month, except at the South. See that frames and sash are in readiness, and do all painting and glazing in season: read note for last month.

Horseradish.—Dig wherever the frost will allow. If more is taken up than can be marketed or used, cover with sand, to prevent wilting. If a new bed is needed, save the crowns for planting out.

Manure.—Have a supply of stable manure ready against the time for making hot beds. See that fertilizers from every source are saved. Compost heaps should be turned over and well mixed. For large gardens manure may be carted to the places where it is to be used, and placed in heaps.

Pea Brush and Bean Poles should be provided in sufficient quantities to meet all anticipated demands. The old stock that has been exposed to the weather, had better be burned.

Prune currants and gooseberries, if neglected in the Fall—cut judiciously so as to leave the bush well balanced. These are too valuable to be absent from any farm or other garden.

Rhubarb.—If new plantations are needed, make preparations to operate as soon as the ground can be worked, or the plants will get the start of you. Give room enough; 4 feet each way is none too much. Give plenty of manure; there is no danger of over-feeding. Remove the earth from the crown of the old plants, and take off with a sharp spade a bud with a portion of root attached. The roots are very brittle, and should be handled with care. Get early supplies by placing a few roots in boxes of earth in the green-house, or by covering some of the plants in the bed, with a box or barrel open at both ends. Fresh stable manure is piled around this, and the heat will soon cause the plants to start. The box or barrel should only be covered when there is danger of frost. If roots are not accessible, try the seed from our free distribution.

Seeds.—Overhaul and supply deficiencies—send orders to the seedsmen early. Those who can afford it, can try, as we have done for some years, every novelty that is offered. For the guidance of

those who have had no experience, a list is given on another page, of the varieties we have found to be of good quality. Better be at a little trouble to obtain seeds from reliable sources, than to buy from irresponsible peddlers, who too often carry old seed around, because they can buy it cheap. If a large stock of some favorite variety was secured from the garden last year, distribute freely to the neighbors and thus encourage raising good vegetables.

Seed Drill.—No garden of any considerable size should be without a machine for sowing seeds. Planting large patches by hand is slow and back-aching work, and it is not done as well as by a proper machine. There are several contrivances for the purpose. We have used the "Wethersfield Seed Sower" for several years, with satisfaction.

Tools.—Make all needed repairs now. Get out an extra supply of hoe and rake handles, unless it is cheaper to buy them. Paint all the wooden parts which need it, and have everything in readiness. In purchasing new tools get the best, at any price. A few hours of time gained will well repay the difference in cost between a good and poor implement.

Flower Garden and Lawn.

Unless the weather is mild enough to admit of transplanting, but little work can be done in these grounds. Still they should be watched to see that any damage from winds or snow be avoided or remedied. The borders present a dreary appearance at this season. Recollect in the planting season to provide against this, especially if they are where they are visible from the house. The borders may be made to wear a cheerful look, even in Winter, by a judicious introduction of evergreen shrubbery, the foliage of which will set off the flowers in Summer, and be pleasant to look upon in Winter. The Holly-leaved Barberry, Rhododendrons, Tree Box, Laurel, Daphne Cneorum, and others, according to the locality, may be used. Make all projected improvements on paper, and if the place is large, and the means warrant it, call in the services of a landscape gardener.

Cold Frames need to be properly ventilated. Give water only when absolutely necessary; remove decayed leaves. Guard against the entrance of mice, and cover from frost in cold weather.

Evergreens.—See that the branches are not broken down by accumulations of snow. Large snow banks will be apt to break the lower branches as they settle; avoid this by shoveling away.

Hot-beds.—Make all necessary preparation. Where early annals are wanted, they may be started in the latter part of this month, but it is better to wait until the next.

Labels and Stakes.—Prepare an ample supply during the stormy days.

Manures may be collected and carted out.

Protection.—Inexperienced persons are apt to remove this as soon as they think the severity of winter has passed. Many things require protection, not on account of the severe cold of our climate, but from the sudden alternations of heat and cold in Spring. If the straw or other covering has been torn off by the wind, have it replaced. A warm spell this month may induce some things to start too early. Shade these from the sun. See article on straw mats p. 49.

Shrubbery.—Have an eye to it after a heavy fall of snow. In mild weather pruning may be done. Pruning does not mean an indiscriminate cutting at a hush. Those shrubs which flower on the new wood, should be cut in a way to induce a vigorous new growth. Many flower only on the wood of the previous year, and should be only sparingly thinned when the branches are too crowded.

Transplant shrubs and deciduous trees whenever the ground is in suitable condition for working. Determine beforehand, what the effect will be, before you plant out or remove a tree or shrub.

Trellises.—Repair old and make new ones. If

disposed to try your hand at ornamental work, choose simple and graceful forms rather than elaborate ones. Study what the effect will be when covered with vines.

Green-Houses.

These will require but little to be done beyond what was indicated last month. Now that warm days are likely to occur, care should be taken to air freely. The temperature should be maintained as uniform as possible, and should never get above 45°, where plants are merely kept, not growing at present. In case of a cold spell, fire heat will be needed. In giving air be careful to avoid a draft.

Bulbs which are growing, should be placed near the glass, to secure healthy growth and strong bloom.

Decayed Leaves.—These should be carefully removed, as they are not only hurtful to the plants, but detract from the neat appearance of the house.

Insects.—Keep up a constant war upon these, by fumigation with tobacco, solution of whale oil soap, and other destroying agents.

Mice.—These often cause great trouble in the green-house; they are very fond of carnations and many bulbs. Set traps or keep a cat.

Prune plants which need to be brought into shape.

Repot all plants needing it. Have plenty of earth and drainage material always in readiness.

Top-Dressing.—Loosen the surface of the soil in the pots, and where it is moss-covered, replace it with fresh earth.

Water.—Use but sparingly, increasing the quantity as the plants commence to grow.

Hot House and Conservatory.

If the weather continues as variable as it has been, extra care will be required to maintain a proper temperature. The sun's rays have now become more powerful, and as many plants have commenced a vigorous growth, great care should be taken to prevent checking this by a sudden cold.

Air should be admitted by the upper ventilators whenever the thermometer shows a temperature of 75° or 80°—currents of cold air should be avoided.

Annals.—Those required for early planting or for growing in pots, may be sowed, such as Balsams, Rhodanthe, Nemophilas, Leptosiphons, Cobea, Maurandia, etc.

Azaleas are now in flower, and require more water and frequent syringing. Young plants should be repotted.

Bedding Plants.—A good stock of these should be propagated. Verbenas, Petunias, Pelargoniums, Ageratums, Gazanias, Lantanas, and the like, will be in large demand at the season for planting out.

Bulbs.—A constant succession of bloom should be kept up by bringing in from the reserve stock in the green house.

Camellias.—These should now be rewarding the care of the cultivator by abundance of flowers. Keep the foliage clean, but avoid wetting the petals. Look out for the red spider.

Carnations, need turning frequently to prevent them from drawing over towards the light. Give water more freely. Propagate by cuttings.

Fuschias.—These are now pushing their growth, and require an increased amount of water. Put in cuttings—especially of hardier kinds for bedding.

Insects need watching to prevent them becoming "masters of the situation." Freedom here is only preserved by eternal vigilance.

Pelargoniums need more water now that they are growing. Cuttings may be made. If attacked by the green fly, they need fumigation.

Repotting.—This will be necessary with quick growing plants. Gloxinias, Gesnerias, and others, require plenty of pot room in order to flower well.

Verbenas intended to flower in pots, will need their final shifting.

Syringe often to maintain proper moisture in the atmosphere. Wet the walks if the air be dry.

Water, should be given according to the demands made by the foliage. Recollect that an excess is as injurious as too little. Avoid the use of water colder than the air of the house.

Grapery and Orchard-House.

In this latitude, cold graperies and orchard houses will require little attention during the present month. The temperature should be kept low, and injury from dampness guarded against. In houses where a moderate heat is employed, the vines may be put up and the inside borders watered with liquid manure. When growth commences, it should be followed up by judicious pinching in. Sprinkle occasionally, and keep the temperature at 45° or 50°. In forcing houses the vines are in all conditions of forwardness, and it is not possible to give particular monthly directions for these.

Apiary in February.

Observe the directions given last month. Sufficient ventilation should be allowed, and the air passages kept open. During the warm days, the bees will be disposed to fly, and they should be permitted to do so, except where there is newly fallen snow. Weak hives should be protected against the raids of marauders, by closing the entrance so as to allow but a single bee to pass at a time. Cleanliness should be preserved by sweeping off the floors; thus saving the bees the labor of removing the rubbish themselves. Guard against vermin as directed last month. If a new bee-house is to be built, it should be done during the fine days of the present month. This is the proper time to purchase bees; the hives are most readily brought home when there is snow upon the ground. Hives weighing from 35 to 40 pounds are to be preferred to heavier ones, provided there is a good cluster of bees. The hive should be carried upon a spring wagon or sleigh, and should be inverted. A piece of thin muslin is to be tacked over the mouth of the hive. When they are placed upon the stand, the hives should be at least 4 feet apart; six feet would be better. Weak swarms need to be fed. It is best to take the hive to a dark warm room, and place the honey where the bees will be sure to find it.

Selection of Garden Vegetables.

The following list is given to aid novices in gardening, in making a selection. Many in looking over a large seed catalogue, are apt to be confused with the great number of varieties presented to their choice, and we enumerate such as we know from experience to be good of their kind, and worthy of cultivation. Those marked with a * are on our list of seeds for free distribution:

BEANS, DWARF OR BUSH.—Early Valentine, for string or snaps; Yellow Six Weeks, do. do.; Dwarf Horticultural, for early shelling.

POLE BEANS.—Large Lima, in warm locations; Small Lima, North of New-York.

BEETS.—Early Bassano*, fine and early; Long Blood, for main crop; Swiss Chard, fine for greens only.

CABBAGE.—Early York, small but early; Early Sugar Loaf*, large and early; Early Ox Heart, do. do.; Winningstadt, medium early, large, very hard heads; Flat Dutch*, for winter; Red Dutch*, for pickles; Marble-head Drumhead, very large; Green Globe Savor, small and late, the richest of cabbages.

CARROTS.—Early Horn*, Long Orange*, for main crop. CAULIFLOWER.—Early Paris, fine; Thorburn's Nonpareil, superb; Large Asiatic, fine, late.

CELERY.—Early White Solid, for earliest; Giant White Solid, for late crops.

CORN.—Dwarf Sugar, small ears, 4 feet high; Darling's Early*, good; Stowell's Evergreen*, fine late.

CUCUMBERS.—Early Russian, small, early, and prolific; White Spined, best for table; Long Green, for pickles.

Egg PLANT.—Long Purple*, earliest; N. Y. Purple, large, but late.

ENDIVE.—Green Curled, for Summer and Fall salads.

KALE.—Green Curled Scotch*, winter and spring greens. KOHL RABI*.

LEEK.—Large Flag, for soups.

LETTUCE.—Curled Silesian, for earliest; Neapolitan*, large and solid; Ice Drumhead, fine; Butter, superior. MUSKMELON.—Fine Nutmeg*, see Seed List, Jan. No., p. 4; Jenny Lind, very early; Green Persian, large and good; White Japan, the best.

WATERMELON.—Mountain Sprout, productive and early; Ice Cream*, very fine; Black Spanish, fine but later. ONION.—Large Red; White Portugal.

PARSNIPS.—Hollow Crowned*.

PEAS.—Princess, extra early and fine, 2½ feet; Daniel O'Rourke*, do. do. do.; Tom Thumb, productive, 8 to 10 inches; Bishop's Long Rod, fine dwarf, 18 inches; Champion of England*, for main crop, 5 feet; White Marrow-fat, later and fine, 5 feet.

PEPPERS.—Squash for pickling; Sweet Mountain, for stuffed pickles.

POTATOES.—Ash Leaf Kidney, early, productive, and good; Early Shaw, early, productive, and good.

RADISHES.—Early Scarlet Turnip*; Long Scarlet Short Top.

SALSIFY.—Vegetable Oyster.

SPINACH.—Round Leaved*, for early; Prickly, for wintering over.

SQUASHES.—Summer Crookneck, best early; White Scalloped Bush, early and productive; Boston Marrow, Fall and early Winter; Hubbard*, fine keeping; Vow-Vow, new and fine.

TOMATOES.—Large Round Smooth, early; Fejee, or Italian*, fine and productive; Pear Shaped, for preserves, etc.; French Tree, late, stocky, curious.

TURNIPS.—Early Dutch, very early; Red Top Strap-leaf*, for Spring and Fall; Yellow Swedish, or Ruta Baga, for keeping.

WINTER CHERRY.—For sauce and preserves.

Containing a great variety of items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

Another Agriculturist Editor.—We are glad to be able to announce that the readers of the *American Agriculturist* will hereafter enjoy the benefit of the constant labors of Prof. Geo. Thurber, in addition to the previous editorial force. Prof. Thurber is well known as an efficient Botanist and Naturalist, engaged by the Government during the extended Boundary Survey between the United States and Mexico in 1850 to 1853; as editor of that valuable work, "American Weeds and Useful Plants;" and during three years past as Professor of Botany and Horticulture in the Michigan State Agricultural College. Some years since we solicited from Dr. Gray a series of elementary articles on plants, of a popular and useful character. His reply was, that his engagements did not admit of it, or he would gladly accede to our request, but that Mr. Thurber could execute the work better than any other one he knew of. We were then unable to secure the desired aid, but as soon as our new associate gets well into the editorial harness, we shall feel relieved of some labor at least, and our readers will doubtless be profited.—O. J.

Advertisements, "Vineland Lands."

Several subscribers write asking if they are to understand the admission of the Advertisement of the "Vineland Lands," as an endorsement from us of all that is claimed for them. We answer, No, we do not endorse this nor any other advertisement, unless it be specially done in an editorial notice. If we could visit every plot of ground offered for sale, and thoroughly examine the soil, the title, etc.; if we could look into every advertiser's books, and mode of doing business; if we could in spect every tree and plant and other thing advertised, then we might give a general endorsement. Our rule is: to exclude advertisements of articles or enterprises, known or supposed to be humbugs, though such usually can afford to, and do offer the best pay; all patent medicine nuisances; advertisements from unknown parties, unless they furnish references of their integrity; also from those who by public repute, or from our own knowledge, are suspected of dealing dishonestly with their customers. Our aim is to try to shield our readers from imposition and deception, even in the advertising pages as well as in the editorial columns. From the nature of the case, however, we can not always thoroughly sift all that goes into the business pages, though we believe the censorship in this department is quite as rigid as that of any other journal, not excepting the professedly religious press.—In regard to "Vineland," as stated in November,

we have not found it practicable to visit or examine the locality in person but hope to do so when the growing season comes round. After considerable inquiry we found no reason for excluding the advertisement, and therefore admitted it.

The Fruit Growers' Meetings are increasing in interest. Except at the Biennial gathering of the American Pomological Society, we never before saw together so large an assemblage of real fruit talent, with so little of charlatanism, as at the meeting held at the *Agriculturist* Office on Jan. 8th. The meeting on the 16th was also well attended, notwithstanding the rain storm. A President is appointed at each meeting for the next week, who calls the assembly to order, and takes charge for the day. Specimens of fruit, etc., are brought in and tried and discussed; committees report on the best varieties for culture, and their reports are thoroughly canvassed; modes of cultivation, etc., are talked over. In short, anything pertaining to fruit growers, and kindred topics, is in order. It is not a good place to introduce and advertise any man's personal hobby, though anything of a valuable or promising character is fairly treated. The discussions are in the form of familiar conversation. We cannot find room for full reports; all said at any one meeting would fill half a number of this journal. The results arrived at we will endeavor to give, from time to time, with occasional more detailed reports. A brief report is given on page 51, and another one of the meeting, on Jan. 15, is crowded out from this number.

Another Monster California Pear.

—Every one doubtless remembers the excitement over the great California pear produced a few years ago, in the orchard of E. L. Beard, Esq., at San Jose Mission; its weight was over three pounds. Rev. Dr. Bellows, President of the Sanitary Commission, has just received notice, via overland mail, that another pear, from the same tree, weighing an ounce more than the former one, has been forwarded to him by the steamer leaving San Francisco Dec. 20, together with other interesting horticultural products. Dr. Bellows has kindly proposed to place the pear, etc., on public exhibition at the office of the *American Agriculturist*, instructing us to receive the package from the Express Office on its arrival. We shall look for it with interest, but the steamer is already several days over-due, and we fear it may have met with some mishap—perhaps fallen a prey to the piratical "Alabama." If the box reaches us safely, the fact will be announced in the daily papers of the city. The interest Dr. Bellows has taken in the welfare of our soldiers, and the pleasant interchange of courtesies in connection with the munificent gifts of the Golden State to the Sanitary Commission, has doubtless led to the sending of these interesting horticultural products to him.

Agricultural College of Pennsylvania.

—We have received the Fourth Annual Catalogue of this Institution. The Faculty consists of five professors with two assistants. Besides these there are several superintendents in charge of the farm, garden, and other departments. During the last session it has had 110 students, nine of whom graduated. Upon looking over the titles of the theses of the graduates, we find that they are all upon subjects relating to practical agriculture. The catalogue gives the standing of each student in the different studies, and also in manual labor. The officers of the College feel encouraged at their success thus far. The next session opens on the 18th of February. The terms are \$100 in advance for board, washing and tuition for a term of ten months. Letters of inquiry should be addressed to Dr. E. Pugh, Agricultural College, Center Co., Penn.

Humbugs to be Avoided.

—Just at this season, or a little later, there usually appear extensive advertisements and printed circulars without number, announcing new seeds, "Egyptian Corn," "Japanese Wheat," "Tasmanian Oats," "Tree Cotton," "Northern Coffee," etc., etc. It will be safe to let somebody else go into the speculation and make his fortune first. Last year a new Agricultural paper was started in this city, claiming great age, and offering unprecedented premiums to Postmasters and others, and a few numbers were issued. We judge, from the numerous inquiries addressed to us, that a good many did not get the premiums, did not get the papers, and cannot get any reply to letters of inquiry about their money. Some parties, not in the best repute, are buying up grape vines, refuse trees, old seeds, etc., and offering them "dog cheap," or for no money. But the varieties of humbugs are too numerous to specify. The better way is to buy what is wanted, of parties of known reliability. The new plants from the Old World will not be first heard of from an out-of-the-way, unsettled place in the far West—nor always from New-York City.

American Short-horn Herd Book, Vol. VI.—Owing to the disturbed condition of the country, the Vth Volume of this standard work was not called for so extensively as expected, and the compiler had concluded to suspend the preparation of Volume VI, for the present. He writes, however, that numerous applications to have the work go on, have been received from the more spirited Short-horn Breeders, and that if a sufficient number of pedigrees are offered, and a corresponding number of books subscribed for, to warrant the undertaking, the Sixth Volume will be issued as soon as the pedigrees can be received and compiled. We hope this will be done; it would be a pity to suspend the regular biennial issue. The temporary depression in the value of this noble race of cattle will not long continue, and the purity of their breeds, and the perpetuation of their lineage should be carefully guarded. Every Short-horn breeder is interested in keeping the blood and lineage of his herd on an indisputable record. The form and terms of application will be the same as hitherto, and we hope every one interested in the matter, will speedily communicate with the Editor of the work, Hon. Lewis F. Allen, Black Rock, Erie County, N. Y.

Mangers Dangerous to Horses.—“S. E. G.” Norwich, Conn., writes that the manger for a horse should be boarded down to the floor, to prevent the possibility of injury to the animal by getting his head underneath it. The lack of such a precaution cost him the eye of a valuable horse, and three of his neighbors had their horses' heads caught fast under the manger.

To Prevent Over-reaching.—S. Edwards Todd, in the Boston Cultivator, after having tried the plan successfully, recommends to hold up the head of over-reaching horses with a check rein. This he says throws the center of gravity of the animal further back, gives more work for the hind legs to do, hence they are not thrown forward against the heels of the front shoes.

Many Pigs.—A correspondent writes that I. J. Halsted, Douglass Co., Ill., owns a sow that brought forth 19 pigs on the 18th of December last. He asks “Who can beat it?” The same mail brings a letter from Wm. B. Lord, Kendall Co., Ill., saying that he knew a sow in Windham, Conn., which had three litters between April 4th 1848, and March 1st 1849, numbering 17, 23, and 27!—67 pigs in 11 months!!! That's the biggest record yet; to beat it, some one will have to invent a story.

Pumpkin Seeds Medicinal.—“J. L. R.” Jefferson Co., N. Y., inquires why Pumpkin Seeds are more injurious to cattle than sorghum, green clover, etc., which also increase the amount of urine. For the reason that the seeds contain a medicinal principle which stimulates the kidneys, thereby causing an unnatural secretion of urine from the blood. They are often used as a diuretic in domestic practice. Succulent plants, as sorghum, etc., probably cause increased flow of urine, because of the large amount of water they contain.

Poultry Wanted.—We have frequent inquiries for fowls of different breeds, from those wishing to purchase, which we are often unable to answer, for want of time or of information as to where they can be procured. Those engaged in raising them for sale should advertise.

Drills Better than Hills.—T. J. Hollingsworth, Armstrong Co., Pa., writes: Last Spring I plowed nearly 2 acres of sod, part of which was mostly sorrel. I marked out the rows about 3 feet apart. As an experiment, we planted 8 rows in drills, the grains one foot apart. We also had 8 rows on each side planted in hills 3 feet apart and 3 grains in a hill. All received the same cultivation. At husking the 8 rows planted in drills turned out 10½ bushels of corn, the other 16 rows—8 on each side, turned out 8 and 9 bushels respectively.

Loam for Composting.—“R. G.” If dried peat or muck is not at hand, use virgin loam, as dry as possible, to mix with your putrescent manures. For a worn out soil, this simple loam is worth carting a long distance. Spread this alone upon a rod square of poor pasture land in the Spring, and its effects will be visible all Summer.... It is doubtful whether night-soil disinfected by sulphuric acid or sulphate of iron, etc., will produce as good and reliable a manure, as when mixed half and half with maiden earth.

Manure for Lawns.—L. D. Peters, Chautauque Co., N. Y. The constant mowing of the grass upon lawns makes it necessary to replenish it with manure. Yet nearly all manures bring in foul weeds and coarse grasses. To meet this difficulty, some gardeners use soot, scattering it broadcast and very thinly, in the

Spring. It is a powerful agent and should be used cautiously. Worms can not abide it. Charcoal dust may also be used to great advantage, and with more safety. This and ashes should be applied in the Fall, so that the snow and rain may wash down the gritty particles below the reach of the scythe.

Northern Rice.—We have had several inquiries for rice which can be grown at the north. A species which grows in India upon dry lands and upon the sides of mountains has been successfully cultivated in some parts of Europe. We do not know that it has yet been introduced into this country. It is a subject which might well receive the attention of the Department of Agriculture at Washington. The “Minnesota Rice” is a native plant which is not confined to Minnesota, but grows along the margins of rivers and in flooded localities, all over the country. It is known as “Wild Rice” (*Zizania aquatica*), is a favorite food of birds and of the northern Indians, who collect it in large quantities.

Chickory.—C. Allison, Jackson Co., O. The seeds of Chickory, or wild endives as it is sometimes called, are to be had at the seed stores. It is cultivated in deeply worked soil in rows 12 or 15 inches apart, and thinned to 8 inches in the row. The plant being a biennial, enough roots should be left in the ground to produce seed the second year. When allowed to escape from cultivation it proves a troublesome weed.

Quack Grass.—A. T. Northup, Otsego Co., N. Y. The plant known by this name, in this country, has a head somewhat like wheat, sometimes with a short beard, and at others beardless. It is sketched in Flint's Grasses and Forage Plants, which figures and describes many useful or troublesome grasses. See our book list.

Cotton from Illinois.—Rev. J. A. Bent, of Washington Co., Ill., sends a sample of his crop, 10 lbs, of unginned cotton. He has had encouraging success, and thinks that in his latitude the cultivation will pay, when ginned cotton will bring 20 cents per lb. The staple of the sample is rather short, but an abundance of this quality would find a ready market.

Sorghum Syrup.—Very fine samples of clear, thick, honey-like syrup are on our exhibition tables, manufactured from cane grown by John Fleming, Hunterdon Co., N. J.

Diseased Pear Trees.—P. Walter, Jay Co., Ind. Your tree appears to be troubled by the leaf blight, which is not regarded as a permanent disease, but caused by some peculiarity of season. It usually occurs after a long warm rain followed by hot sunshine.

Pears—Soldat Labreur, and Duchesse de Berri d'Etc.—“F. T. R.” Ottawa Co., Ohio. The former is considered, when well grown, one of the finest pears of its season—Oct. and Nov. The latter is ripe about the last of August; the tree is a free grower and bearer; fruit rather small but sweet and melting, but not yet sufficiently tested to be recommended for general cultivation. Both these pears are described in Downing's Fruits and Fruit Trees of America, a work which should be in the hands of every fruit grower. We can still supply it, post-paid, for \$2, which is very cheap in these times of high-priced paper, for an illustrated standard book of 760 pages.

Clay for Fruit Trees.—J. J. Joslin, Rutland Co., Vt., asks: “In transplanting fruit trees into a gravelly loam with coarse gravel subsoil, will a bed of clay in the bottom of the hole be beneficial?” We judge not. It would be likely to retain too much water. If danger from drouth be apprehended, it would be better to thoroughly mix a portion of clay with the soil in which the trees are to be set, which would enable it to hold sufficient water without danger of too great accumulation. Mulching around the tree as far as the roots extend will aid in keeping a supply of moisture.

Isabella Grapes in Winter.—Next to Dr. Underhill's, perhaps no Isabella grapes are better known than those produced by E. A. McKay, of Naples, Ontario Co., N. Y. That locality and soil seem to be peculiarly adapted to this old standard native variety. On January 21, we received from Mr. McKay's city agents (Haley & Sayre), a box of the grapes in a good state of preservation, and which would be hard to excel in flavor, and especially in the size of the clusters, and largeness of berry. They were simply laid in a thick paper box, without cotton or other packing material.

Peach on Plum Stocks.—J. Webster, Marion Co., Ill. The peach grafted on the plum succeeds much better in cold damp soils than it does on its own roots. The wild plum is successfully used and makes a very hardy stock. The peach grown on plum stocks, is somewhat dwarfed.

Curculio—A New Remedy.—A. P. Richardson, Norfolk Co., Mass., thinks that his success in preventing the attacks of the curculio is such as to warrant him in suggesting his plan to others. As soon as the trees blossom, their trunks are surrounded by cotton saturated with Kerosene oil. This is placed a foot or two from the ground, and the oil is renewed once or twice a week as long as the curculio continues to appear.

Earth Worms in an Apple Tree.—A correspondent at Franklin, N. Y., writes as follows: “Standing under an apple tree, I discovered a rotten spot in the trunk, above my head, where a limb had formerly been cut off. I commenced digging out the rotten wood with my knife, when, presently, two earth-worms fell from it. How came they there?” A bird may have inadvertently dropped one in a crevice, and the second one may be its progeny; earth containing the worms may have been thrown there. In absence of positive knowledge, one guesses about as good as another. They certainly did not originate there spontaneously.

What Grapes to Plant.—Daniel Chillas, Del., (and several other inquirers,) is informed that the subject of grapes is under consideration by the Fruit Growers' Meeting, held each Thursday at the office of the *American Agriculturist*. We shall publish a list of the varieties they fix upon, in season to be of service to those who intend to plant next Spring. For cheap graperies see *Agriculturist* for September, 1861, p. 272.

Wine from Grapes Only.—At the recent session of the Illinois State Horticultural Society, a committee, to whom was referred the consideration of the expediency and economy of making Wine from Rhubarb or Pie-Plant, recommended that the juice of the Grape alone be designated as wine, and that all liquors, the result of vegetable compounds, be known by such names as will not be likely to confound them with grape products.

Cucumber and Tomato Seeds.—S. R. Parsons, Maine. These seeds may be readily freed from the surrounding mucilage by allowing the fruit to partially decay. If placed in heaps and allowed to heat, the seeds would be injured. The best way is to place them in a box or tub and keep covered with water until sufficiently decayed to allow the seeds to be washed clean.

Vegetable Bouquet.—This must be seen to be appreciated. A finely arranged basket, from B. Stevens, Washington Market, this city, represented camellias, roses, dahlias, etc., cut from vegetables. A turnip, beet, carrot, parsnep, or onion, has one end rounded off, and with a jack-knife, petals are cut out, so natural as to deceive a person at first look. The different colored flowers are then neatly arranged in a flat turnip scooped out for a basket, and with a few green leaves, cranberries, etc., tastefully arranged, they form an interesting and attractive ornament. They soon fade, however.

Dahlias and Asters from Seed.—“E. C. P.” Caledonia Co., Vt., says that where dahlia roots can not be obtained, many have fair success with seeds. A ten cent paper furnished, in four months from planting, a number of very perfect varieties, as well as many worthless ones. The same correspondent adds that double asters, which generally produce very few seeds, may be made to seed freely by pulling out some of the center florets or petals, as they are often improperly called. This practice gives the seeds the needed room to develop.

Mignonette without Fragrance.—S. E. Warner, Fairfield Co., Conn. The trouble seems to be that you grow it on too rich a soil. Use more sand, or work in some poor earth, and the Frenchman's favorite plant will be as odoriferous as you can desire.

Arranging Hyacinths.—John D. Eastwood, Essex Co., N. J. A very satisfactory way, is to prepare a circular bed, say five feet in diameter. Set the bulbs in circles, one color to a circle, and the bulbs about three inches apart. Put the reds in the outer circle, the whites in the next, and the blues in the center. Such a bed viewed across a lawn, has a very striking effect, far superior to a mere melange of sorts and colors. The ground may be filled with annuals or bedding plants, as soon as the foliage of the hyacinth decays.

Cattle Tramping—Curious Figures.

—A wild heifer belonging in the neighboring village, that ought to have been "impounded" for sundry previous misdemeanors, ran through our gate the other day, as it was opened for a carriage to pass. She galloped as if mad, up and down the garden, over the beds of bulbs, across the lawn, among the shrubbery and elsewhere. We called the owner to account for letting this animal loose for the third time contrary to law, and pointed to her deep footprints that spoiled the grass and plants wherever she stepped. He insisted that she had done little harm. The incident set us to figuring the amount of injury done in this case, and generally, when cattle or other heavy animals are allowed to run upon meadows, or fields of grain. Suppose a cow walks once around a square field of ten acres, taking five steps to a rod, and making a separate track with each foot. If the foot tramp down or spoil a surface equal to six inches square, the single journey round will injure 800 square feet. Nine cattle going three times round would spoil half an acre! Let the arithmetical reader of the *Agriculturist* carry out these figures, learn the lesson inculcated by them, and act accordingly, especially while the ground is soft, as it will often be between now and settled weather in Spring.

Too much Kindness to Sheep.—S.

Randall, the well-known sheep breeder and author, gives, in the *Country Gentleman*, his views concerning the great mortality among young lambs in the Spring of 1862. In many sections, particularly of Western New-York, these animals appeared to be wanting in physical development at their birth, and thousands died in a short time thereafter. Mr Randall is of opinion that the difficulty was largely owing to the too close confinement and high feed of the pregnant ewes during the month of February. Fullness of flesh in the mother is unfavorable to the well-being of the offspring before birth. They should be strong and healthy but not fat. It is recommended to allow animals in this condition, succulent food, as roots; to feed sparingly with grain, and not to crowd them in poorly ventilated sheds. They need protection from storms, particularly rain, with plenty of exercise and pure air.

Rabbits in Nursery and Orchard.

L. Vories, Madison Co., Ill. Trap the rabbits and make "pot pies" of them. They are easily caught in a common box trap with sweet apples or potatoes for bait, or they will catch themselves without bait if the trap is properly arranged, as they will run into anything that promises them shelter. Where trees have been gnawed by rabbits, bank up earth about them or blind up with clay or cow manure.

Fruit Stock.—J. H. Creighton, Zanesville, O. The Siberian Crab is of too slow growth to make a good stock for the apple. The pear will not do well on the common or Doucain apple stock.

Fruit Queries.—J. Brownell, Washington Co., Pa. The Bartlett Pear does not succeed as well on the quince as upon the pear stock. Apple orchards should be pruned where the limbs are crowded. June and July are the best months. We have already published a list of pears, and shall do so with other fruits, as soon as they can be determined on. Your best course is to rely upon the judgment of successful fruit growers in your district.

Staking Apple Trees.—Subscriber, Coffey Co., Kansas. Doubtless your trees might be staked without injury to the roots. Trees for such windy countries as yours should be grown with branches very low, in the nursery.

Chenango Strawberry Apple.—T. H., Wayne Co., Mich. This is not much known at the East. One of our best pomologists considers it a good third-rate apple, but worth cultivating on account of its remarkably fine appearance.

Trees on Prairies.—Several subscribers in the far West make queries upon this subject. The answer would be too long for a basket item, and, as all the other pages are filled, the reply must wait till the next month. See article on the Willow, on p. 39.

Grafting the Grape.—L. C. J. Townsend, Mass. The grape is so readily propagated from cuttings and layers, that grafting is seldom practised. The clons should be cut before vegetation starts. The grafting is done when the vine is in leaf, and danger of bleeding has passed. The earth is removed from around the vine, which is cut 3 or 4 inches below the surface. The stock is split and the clons inserted in the usual way of cleft grafting. No wax or other composition is applied but the earth is merely replaced. Another mode has

been recommended, which is to split a large vine at intervals of one or two feet, and insert the ends of the clons, which are cut to a wedge, in the slits. The vine is then buried horizontally so as to leave one or two buds of the clons above the surface. The vine so layered throws out roots during the season, and in the Fall or following Spring may be cut up so as to leave a share of roots to each graft.

Salt for Insects.—"W. C." Wankesha Co., Wis. We very much doubt if sufficient salt can be used to destroy any kind of insects without injury to the vegetation, while the cost would be enormous. A ton spread over an acre would be only a pound on every twenty-two square feet, and that amount worked into the soil would hardly be heeded by insects. A positive statement put forth by a professedly agricultural journal, that a bushel or two of salt on an acre, would destroy the wire worm and other insects, has gone the rounds of the papers for years. This is the third time we pronounce it nonsensical. When land is plowed in the Fall, the frosts of Winter will generally kill great numbers of them.

Green Manure.—L. Z. Snyder, Montgomery Co., Pa. Millet or oats will make a good crop to turn under before sowing fall wheat. At the present price of oats, millet seed will be much the cheapest. If the soil is infested by weeds, buckwheat may be used. Sow early and plow in as soon as it is in flower, and then sow for another crop to be plowed under first, before sowing the wheat.

Chinch Bugs.—"A Reader," Winnebago Co., Ill. The eggs of this troublesome insect are not deposited in the corn, but in the ground, where the young are sometimes found in great numbers. As they are most numerous in dry weather, and disappear after a rain, it has been proposed to shower the crops to destroy the bugs, by means of a fire engine, but this would not be practicable on a large scale, even if it were effective.

Obtaining Seeds from Washington.

—Several inquirers are informed that their best way to procure seeds from the Agricultural Department at Washington, is to make an application through the representative of their own districts, as the seeds are mainly distributed through the Members of Congress.

Seeds Received.—C. H. Howard of Utah sends us seeds of the currants of that Territory, and Wm. Holley of Hall Co., Nebraska has furnished us with the stones of a dwarf cherry of that region. All these have been placed for trial with one of our most experienced cultivators of small fruits.

Seeds for a Name.—W. G. Fowler, O. The plant is *Lunaria biennis* and is called Satin Flower and Honesty. It is cultivated for the delicate membrane which is left after a portion of the pod falls away; this is used in making dry bouquets. It flowers the second year from the seed.

Hubbard Squash.—Robt. Hutchingson, Ashtabula Co., O. The usual shade is a dull, clay blue color. It sometimes is of a dark olive green. Both colors are considered by the introducer as equally pure.

More Beans.—W. C. Comstock of Fairfield Co., Conn., writes that among his beans raised last season, was one plant with 83 pods, containing 456 merchantable beans, of the kidney variety. He planted in drills 10 inches apart, in rows two feet distant.

Red Cabbage.—N. C. Laughlin, Ct. This variety is always small, but should grow larger than the first. The pickle is made by slicing the cabbage, adding spice and pouring cold vinegar over it.

Crimson Clover.—J. F. Rucklman, Munroe Co., Pa. We have only seen this cultivated on a very small scale, and the account to which you refer is the only one we have seen of any extensive experiment. The plant is very showy when in flower. The seeds can be had in this city.

Daphne odora.—Mrs. J. W. H., Charlestown, Mass. This is an evergreen green-house shrub which bears clusters of white or pinkish, very fragrant flowers on the ends of branches. It belongs to a widely different family from the Tuberose and resembles it in odor only. If grown as a house plant, it should not be in too hot a room, and should have plenty of air.

Gloxinias and Petunias.—A Reader, New-Hartford, Conn. These are raised from seed and the varietals continued by propagation from cuttings.

Gloxinias can be successfully raised only where there is a green-house. Petunias are readily grown in the open air. The seeds may be had at the seed stores, and a paper may give you some fine double ones, but if you wish to be sure of these, the best way is to get the plants from commercial gardeners.

Camelina sativa.—A. K. Laughlin, Vt.

We have no knowledge of the culture of this plant for its oil in this country. The article in the Patent Office Report was copied from an English journal. It is known by the names of False Flax, Wild Flax and Gold of Pleasure, and is only known in this country as a not very common weed in old fields.

Nemophila maculata is the plant sent by Mary Rider, Holmes Co., O. It is a native of California. The vulgar name is Spotted Lovegrove. This, with the *N. insignis*, *discoidalis*, and others, are among our most beautiful annuals.

Truffles—Tuckahoe.—Geo. H. Gilbert, of Cheshire Co., N. H., in response to the query, whether Truffles were ever found in this country, says that 12 or 14 years ago he was living in Mississippi, and there frequently saw a kind of root that grew in the ground entirely unconnected with any plant or leaf above the surface; it was about 1½ inch in diameter, and 3 inches long, looking quite like a sweet potato. Pigs were fond of them, and he supposed they were a species of Truffles. The substance he refers to is doubtless the "*Tuckahoe*," or Indian bread, a thing which has been a great puzzle to naturalists. It has been classed with the Fungi (Mushrooms) and has been called *Lycoperdon solidum*, but as no vegetable structure has been discovered in it, its real nature remains unsettled. The Tuckahoe has been found as far north as New Jersey.

Dairy Farmer.—California subscriber. There was such a paper published, but owing to the times it was obliged to suspend—temporarily we hope.

Ag'l. Library Association—A Good Move.—J. J. Joslin, Rutland Co., Vt., writes that an Agricultural Library Association has just been formed in the town where he resides, and agricultural works amounting to \$250 are already purchased. A "Farmers' Social Club" for discussing appropriate subjects, is connected with the association.

Economical Food.—"Diffidence," of Middlebury, Vt., writes as follows: "In these times of patriotic sacrifice and diminished incomes, many of us would like to learn how to live comfortably on a small sum. No doubt you have many subscribers like myself, not farmers, who take your paper for its other valuable contents. Will not some kindly disposed lady reader, who has to purchase everything for the table, with little enough money to do it with, give a list of the 21 meals, such as are eaten in her family for a week? With such a list in the *Agriculturist*, no doubt many of us would be much benefited." [We shall be glad to have responses to the above.—Ed.]

How it Paid.—The letters on business, and other topics, received at the *Agriculturist* office, number from 75,000 to 100,000 a year. A single morning's mail, sometimes brings in more than five hundred. These letters very often convey hints and suggestions which are of indirect aid in preparing the paper, when they are not used directly. The letters for two months past have, more than ever before, abounded in kind words of approbation and encouragement, indicating such a spirit of friendly feeling on the part of our readers, as we greatly appreciate and enjoy. Hundreds, perhaps thousands, have recently given an account of some special way in which a single hint from the paper has paid them far more than the cost of it for a year. We take the liberty to give the substance of a private note from a subscriber (J. M.) in Shiawassee Co., Mich. "....Three years ago an auction of bees was to be held, which I had no thought of attending, until just before the sale I happened to read an article on bees in my *Agriculturist*, which led me to buy 13 swarms that averaged \$3 each (\$39). The two heaviest I traded for a 3-year old steer which I sold for \$24, leaving the cost of 11 swarms, \$15 net. The first two years I took up 7 swarms, and last Autumn 12 swarms more, and a nice lot of cap honey which altogether paid more than five times over for the care of the bees, and I now have 26 swarms left, which I would not sell at \$4 each or \$104; so much for the \$15 invested. This will pay for the *Agriculturist* longer than I shall live. I am wholly indebted to the paper for my bees, to say nothing of many other good ideas obtained from it, too numerous to mention. The paper is certainly a good investment at \$1"

The White Willow Excitement.

Numerous letters have been received at the office of the *Agriculturist* asking our opinion on the use of the White Willow for hedges. Our Western exchanges contain loud advertisements of nurserymen, and those who have the cuttings for sale, and the papers have frequent articles for or against its use. We have watched this discussion with interest, in the hope of finding some reliable information on the subject. From all we can gather, and from what we know of this plant, we judge that, as a screen to break the force of sweeping winds, it will answer a good purpose, but that its value as a hedge plant is as yet rather problematical. As it is destitute of thorns, and the small branches are always weak, it can only serve as a hedge by presenting a barrier of trunks. Whether the willow, or any other tree, will grow when planted near enough together for this, we are inclined to doubt. A given area of ground will only sustain a certain amount of vegetation, and the strongest plants will choke and kill out the weaker ones. This happens in nature, and is within the observation of every cultivator. As a timber belt, to serve as a wind screen, there is no doubt it may be employed with benefit.

The following is the method of planting for hedges: Cuttings about ten inches in length, cut at the lower end with a slope, are stuck into the soil, in a slightly inclined position, at six inches apart. The plants are hoed and weeded the first year, and the cattle kept away until they become large enough to resist them.

The white willow makes a large tree, 50 to 60 feet high. The wood is valuable for charcoal, and makes a tolerably serviceable timber. Taking advantage of the present excitement, some persons have cut up the common willow of the swamps, to sell as the white willow. Those purchasing should be on their guard against this imposition.

The Remarkable Winter—Its Effects upon the Wheat and Rye Crops.

Thus far the present Winter has been noteworthy, we might rather say, there has been a remarkable absence of Winter. At the time of this writing, it is past the middle of January, and yet, with the exception of a very few days, early in December, we have had no snow to speak of, and but little ice in the vicinity of this city. Overcoats have been worn more as a safeguard against expected cold that might come on suddenly, than as a necessary protection from cold actually experienced. Similar weather has prevailed over the country generally, though in a few localities snow has fallen more abundantly. In two respects this weather has been highly favorable to farmers and others. There was so short a crop of hay in many places that apprehensions were entertained in regard to the possibility of carrying the usual stock of animals through the Winter. But mild weather has saved an immense amount of forage, for it is a well understood fact, that in very cold weather, a large proportion of the food consumed by man and beast, is required to keep up the heat of the body. An animal needs nearly double the quantity of food when the thermometer is at zero, than is required when the temperature is at summer heat. Should the season continue thus mild and open, hay will be abundant and cheap during the spring months. "Winter never rots in the skies," is an old adage that generally, not always, holds true, and it will be fortunate for those having short supplies in their hay mows or stacks, if we do not have severe cold weather all through February and March, and late into April. In the Eastern and Middle States, where coal is extensively used, the supply was unusually short last Autumn, and prices were nearly double what they were a year before. This mild weather has greatly favored all who depend upon coal for fuel. Owing to the small amount of fire needed, it has cost less than in ordinary years to keep the dwellings warm.

But we entertain serious fears concerning the effects of this weather upon the winter grains,

wheat and rye. A continuous frozen condition of the soil does not injure these crops, while a mantle of snow maintains a somewhat uniform temperature, and is highly favorable. The alternate freezing of the surface at night, and thawing out by day, which has been the order for two months past, must have done great damage to the wheat plants. Many of them have doubtless been killed already, and should this weather continue, we fear the result will be disastrous. Little can be done to help the matter. Those having an abundance of manure, or of straw that will not be used for feeding or bedding, may find it advantageous to cart it out and spread it upon the wheat fields, if they chance to be frozen sufficiently at any time to prevent injury from the treading of teams, and cutting by the wheels. A mulch of this kind will partially prevent the frequent changes of temperature. If our staple crop of wheat is to be in part cut off, as it may already be, it behooves farmers to lay out their plans for putting in the largest possible area of spring wheat, where it will grow well, and of other summer crops.

Tobacco Culture—\$30 Offered for Practical Information.

Our assistants report that in at least a thousand letters recently received, there is a call for articles, and especially for a book on tobacco culture. We know of no such work, are destitute of practical experience with this particular crop, and scarcely know where to get the best practical information desired. In order to call out information, we therefore propose the following cash premiums:

For the Best Essay on Tobacco Culture.....\$15.00
For the Second Best Essay.....\$10.00
For the Third Best Essay.....\$5.00

The essays to be written by those who speak from practical experience or observation; to contain full directions for culture and treatment; from the securing and sowing of the seed to the harvesting, curing and marketing of the crop; the best variety, etc. Fifteen pages or less of foolscap paper will suffice for this; the less space occupied, the better, if particulars are given sufficiently full to meet the wants of those entirely inexperienced. The essays in our work on Onion Culture, (see page 61), are good examples of what is wanted. Any illustrative engravings required, will be made at our own expense, if the outline sketches be furnished by the parties who write. The essays to be delivered at the *Agriculturist* office on or before March 1st. The sooner they can be on hand, the better, that the Committee may have time to look them over. The essays will be submitted to a competent Committee, and the prizes paid according to their award. One or more of the best essays will be published in the April *Agriculturist*, and, if a sufficient number of good articles are offered, they will be issued in cheap pamphlet form, early in March, to meet the requirements of the present year. In order that we may do this, we make it one condition of the offer of the prizes, that we have the right to publish any articles submitted. (Ten copies of any pamphlet or book issued, will be at the disposal of each person whose contribution is inserted, whether he obtain one of the prizes or not.) The writer of each essay will please enclose his name and full Post Office address, in a sealed envelope, along with his manuscript. Fine literary style is not so much desired as to have the directions fully and plainly given;

we will put the writing into proper shape for publishing. If those who wish to compete will notify us at once, we can probably announce next month whether a pamphlet will be issued.

Maple Sugar.

This product, which, if properly made, always commands a good price and ready sale, will this year be especially valuable, owing to the high cost of every kind of sweetening. Those having even a few trees, will do well to make the most of them, by commencing to tap as soon as the sap will flow. In many localities a large run may be had the latter part of the present month, unless the Winter should be protracted unseasonably.

Immediate preparation should be made for the work, particularly where there is a large sugar-grove. In such cases it will doubtless pay to procure one of the evaporators intended for Sorghum syrup, but which are equally fitted for sap boiling. Cook's is certainly good. It was used in this way to some extent last year, with entire satisfaction. Samples of sugar and syrup made with it, received at the *Agriculturist* office, were of the very finest quality. (See advertisement in Jan. No.) Shallow sheet-iron pans, which can be made at the tinman's, will be found much more economical than the deep kettles frequently used. Provide a good supply of dry fuel convenient to the boiling place. A shed to enclose the arch and kettle will add to comfort and cleanliness. Buckets of tin are lightest to carry, but are apt to be rusted during the year, which would impart a dark color to the syrup and sugar. Unpainted pails, of cedar, pine or white-wood, are generally preferred. These, with the evaporator, the spouts, and everything connected with the manufacture, should be kept scrupulously clean. The need of clarifying syrup, arises mainly from neglect in this respect; the best specimens we have seen were made without the use of any substance to remove impurities—none were suffered to be mixed with the sap.

Fig. 1.

Spouts are readily made by removing the pith from pieces of elder, or from foot lengths of inch square pine. For the latter, remove the upper half to within two inches of one end, bore or burn a one-quarter inch hole through the thick part left, and cut a groove from the hole to the other end, as in fig. 1. If elder stalks are accessible, good spouts are made as illustrated by fig. 2, by sawing half through at *a* and *b*, and splitting between the cuts. Each piece then makes two spouts.

Fig. 2.

A three-quarter inch auger bit is best for tapping, which should be done on the south side of the tree, boring the hole about one inch deep.

It saves time after the boiling is commenced, to have a constant stream of sap trickling into the evaporator, and the thickened syrup discharging into a second vessel for "sugaring off." Otherwise, the sap collected must wait until the first lot is finished. In the latter part of the season it readily sours, and may soon spoil. It is well to add a little lime to the sap during the last running, to neutralize any existing acid.

No Time to Run in Debt.

An Ohio Reader asks: "Would you consider it prudent for a farmer having a hundred acres paid for and well stocked, and out of debt otherwise, but not having a comfortable domicile, to incur a debt of five or six hundred dollars in building a dwelling house?"—We think not. In the November *American Agriculturist*, we referred to the effect of the increased relative value between gold and currency, and showed why farmers should seize upon this time to get out of debt and keep out. The recent further advance in gold gives additional force to the reasons then set forth. Currency that will pay debts is now very abundant and will probably be more so for a time. The moment the war closes, or bids fair to close, the country will begin to turn to a specie currency; and then look out for breakers. What now is called \$150 will begin to recede toward \$100. A debt of \$100 contracted now, when wheat is at \$1½ per bushel in this city, will probably have to be paid, when wheat will be worth only \$1. This will not probably take place at once, for there will be a large amount of "legal tender" currency to be retired from circulation before specie will be the legal standard, but the change must sooner or later take place. If the old house is at all tenable, or can be made so with a little outlay, better put any surplus funds aside, where it will be absolutely safe and can be called in dollar for dollar. Then when prices of labor, of timber, and of other materials fall, the money and its interest can be used to far greater advantage. If there be a mortgage upon the farm or house, poor crops and low prices may perhaps not enable you to meet it. This flush period is just the time to get out of debt, keep out, and lay by as much as possible.

Mutton Trade of New-York.

145 MILES OF SHEEP.

Few persons are aware of the extent to which sheep are sold in this city. Including those received at the four public market places, and those sent directly to butchers, an average of over 10,000 live sheep per week were slaughtered in this city during the past year. Besides these, there are at least 1,000 dressed carcasses received weekly. If the whole number were driven in at one time, three abreast, allowing four feet of space for each sheep, the line would extend from New-York to Albany, a distance of over one hundred and forty-five miles.

Since the commencement of the war, the demand for wool has so greatly increased that farmers are adding largely to their flocks. They find that, with the high prices of wool and the good demand for lamb and mutton, sheep-raising is one of the most profitable branches of farming, and they are now holding back their stock. Prices vary somewhat with the supply, but well fed sheep, which will weigh 100 lbs., alive, have been selling at \$5½ a \$6 per head for a month past; they are now (Jan. 15th) worth \$6½. The rise in wool has added largely to the value of pelts, mixed lots of these selling at \$2½ each, and selected pelts at \$2½ each.

In former years the thin ewes have been bought up by farmers for store sheep, at \$2½ a \$3 per head. Of late this class has been mostly kept in the country. Those sent to market have been bought up by butchers at \$3½ a \$4 each. Contrasting with this class are a limited number of extra large fat sheep, usually sent in about

the holidays and sold at high prices. A few have brought as high as \$15 a \$20 each. Three full blooded Leicester sheep, from Canada, were recently sold to a butcher of this city for \$70. They dressed 471 lbs. The pelts would bring \$2½ each, which would leave the cost of the mutton a little over 12 cents per pound. In view of these figures it is safe to advise the raising of more sheep and fewer dogs.

Breadstuffs, Meat, etc., for 1862.

All classes of readers will be interested in the two statistical articles given on pages 58 and 59. The tables have been specially prepared for the *American Agriculturist*, with great care and no little labor, and they are arranged to show at a glance the amount of transactions in some of the leading articles of farm produce in the great central market of the country for the year 1862. A comparison with the previous three years is also given, together with tables showing some of the transactions in breadstuffs at Boston, Philadelphia and Chicago. The following table shows the receipts at New-York of the leading articles of Grain, with the prices and total sums paid for them. This table includes only the amounts received through regular channels and recorded at the Corn Exchange or Custom House. Large amounts, not here included, having been sold "to arrive," have gone directly to receivers without being recorded, while other amounts have come in by irregular routes. The prices in this estimate are the average of the average prices on the 20th of each month, as given in the second table:

RECEIPTS AT NEW-YORK FOR 1862.

Kind.	Amount.	Average Price.	Value.
Wheat Flour.....	5,757,608 bbls. at	\$5.71	\$32,875,941
Wheat.....	27,079,259 bushels at	1.37	37,098,584
Corn.....	17,290,234 bushels at	.64	11,065,748
Rye.....	932,084 bushels at	.83	773,629
Barley.....	1,151,818 bushels at	1.05	1,209,408
Oats.....	5,051,874 bushels at	.50	2,525,937

Total for Flour, Wheat and other grains.....\$83,549,247
Total amount for same articles in 1861.....\$81,216,567

PRICES IN 1862.—The following table gives the New-York prices of leading articles on the 20th of each month, the date of making up our monthly reports. A careful estimate indicates that for the average of all sales of the different grades, we may take: for *Wheat Flour* the highest quotations for "Extra State;" for *Wheat* the highest quotation for "All Kinds of Red;" for *Corn* the highest quotation for "Mixed;" and for *Oats* the highest quotation for "Western."

NEW-YORK PRICES ON THE 20TH OF EACH MONTH IN 1862.

1862.	Flour.	Wheat.	Rye.	Corn.	Oats.	Rye.	Barley.
	\$ c.	\$ c.	\$ c.	\$ c.	\$ c.	\$ c.	\$ c.

It will be seen by the tables and remarks on page 59, that the receipts of wheat and flour, taken together, were lower in 1862 than in 1861, but the higher prices the past year raised the total product of sales here, to a greater sum.

The *Live Stock Table*, as exhibited on page 58, is also interesting. The total number of live animals destined for slaughter received at the regular yards, reached 1,845,605, or nearly two million head! Of these more than one-half (1,098,712) were live hogs, or about twice

as many as were ever brought to this market in a single year before. But the items are so fully set forth in the article on page 58 that no further explanations are needed here.

The Department of Agriculture.

The doings of the Agricultural attachment of the Patent Office, were so severely criticised by this and the other agricultural papers of the country, that a new Department was created to manage the agricultural operations of the government. With the change we looked for a new policy, one which should be of actual benefit to the agricultural country, and which should not interfere with the legitimate business of seedsmen, nurserymen, and others. Thus far, there does not seem to be strong reason to hope for a change for the better. Two small pamphlets emanating from this Department are before us. One of these is mainly devoted to informing the world what a great country this is, and the other is a catalogue of the Plants, Bulbs, Tubers, etc., which are ready to be sent out from the "propagating garden," of this country noted for its immense resources.

Upon looking over the limited list we find it to be composed, with but very few exceptions, of plants which can be obtained at any nursery. It is gratifying to know that there are ready, 80 varieties of gladiolus—why we have not hyacinths and tulips, and the rest of the bulbs is not mentioned. Then there are 100 specimens of the Mist-bush or Smoke tree (*Rhus Cutinus*), which was introduced into England in 1856, and is to be found in almost every old garden in the country. "A rare old plant is the ivy green," but the U. S. has managed to propagate 600 plants. That novelty, the Chinese Yam, can be found at Washington, and the common Prickly Pear is to be had in small quantities. For the credit of the country, we call upon the authorities to burn up or quietly dispose of their old rubbish, and to stop distributing plants or seeds until they have something which comes within the letter and spirit of the law, and are able to "distribute among the people, new and valuable seeds and plants."

Brine Poisonous—A Caution.

During past years we have published in the *Agriculturist* occasional reports of bad effects from feeding to animals salt from meat barrels. In a recent number of the *Honesdale* (Pa.) Herald, we find an account of the sudden death of several valuable imported hogs after eating food mixed with brine from a beef barrel. In this case the evil effects are attributed to salt-peter (nitrate of potash) used in curing the beef. Whether it was the nitre, or the salt, there have been a sufficient number of instances reported, to render it hazardous to allow any animal to consume either the salt or brine, from any kind of meat. Salt food of any kind is destructive to fowls, and care should be taken to keep them from house slops containing salt. But refuse brine and salt are excellent on the asparagus bed, applied in Autumn or Winter, or at any time except in the cutting season. It even pays to put on a good layer of new salt. Refuse brine or salt is also good on most soils, and on most field or garden crops, and should not be wasted.

Kindness is a language, which not only the dumb can speak, but the deaf can understand.

The Indian's View of Agriculture.

We doubt if a better argument for improved agriculture can be given, than is found in the speech of an Indian chief to his tribe at the West. It ran thus: "Do you not see the whites living upon seeds, while we eat flesh? That the flesh requires more than thirty moons to grow up, and is then often scarce! That each of the wonderful seeds they sow in the earth returns them an hundred fold? That the flesh on which we subsist has four legs to escape us, while we have but two to pursue and capture it? That the grain remains where the white man sows it, and grows. That Winter with us is the time for laborious hunting—to them a period of rest. For these reasons, they have so many children, and live longer than we do. I say therefore unto every one that will hear me, that before the cedars of our village shall have died down with age, and the maple trees of the valley shall have ceased to give us sugar, the race of the little corn-sowers will have exterminated the race of the flesh-eaters, provided their hunters do not resolve to become sowers." History shows the truth of these prophetic words.

A Double Action Root Cutter.

Farmers are beginning to learn the value of root crops, and their increasing consumption has led to the invention of several machines for slicing or reducing roots to a condition for feeding. We present an engraving of a very good one, lately introduced from England. Its novelty consists in the cutting knives. These are of steel, placed on a wrought iron cylinder, (Fig. 1) which revolves in the box of Fig. 2. At the lower part of the cylinder as represented in the engraving, is seen one of these knives extending the whole length,—it has an irregular cutting edge elevated about an inch above the cylinder, and an opening below, which communicates with its interior. The box in which the cylinder revolves has cast iron sides. If the hopper is filled with roots and the cylinder turned in the direction of this cutting edge, they are rapidly sliced by the knife, the pieces passing into the cylinder and falling through its open ends below. There are two knives of this kind which divide the roots into rather large slices, suitable for cattle. For cutting

Fig. 1.

smaller, or finger pieces, for sheep and calves, there are two other sets of knives, one of which is represented in the engraving, at the side of the cylinder. These are stout blades about an inch long, and are placed in the form of

a letter V, with their cutting edges facing those of the large knives. By rotating the cylinder in the direction of these blades, the roots are reduced to quite small fragments. By turning to

Fig. 2.

the right or left, the pieces are cut large or small as may be required. The roots when fed to the machine, are thrown upon an inclined iron grating, which forms one side of the hopper, through the openings of which any loose dirt or small stones may fall out. The machine will readily cut a bushel of roots in from 10 to 15 seconds, is substantial in make, and requires no adjusting, as it cuts fine or coarse by merely reversing the direction in which the crank is turned. The N. Y. manufacturers' price is \$35.

Mulching Wheat.

H. M., of Kent County, Maryland, writes to the *American Agriculturist* as follows: In 1853 I had a field seeded, part of which was a basin of loamy, spongy, black soil. On this portion of the field the frosts of Winter did their work so effectually, that I did not get my seed at harvest. During all the freezing weather the soil looked like a honey-comb; and in the Spring, the wheat which the land had thrown out, might be gathered up in handfuls. In the fall of 1861, I sowed the same land, and immediately covered the whole basin with old wheat straw; last harvest this was nearly the heaviest of the field. Now, for the science of this: I imagine it consists in the fact that the straw serves not to keep the land from freezing, or the wheat from being thrown out, but to protect it from the air and sun, and afford moisture to the roots until they can again fasten upon the soil. It may, however, be that the mulch acts in some degree as a protection from excessive cold. (a.)

One of my neighbors having similar land and looking about for a remedy, was told by a Pennsylvania farmer to sow one and a half bushels of gypsum to the acre on such land after being seeded. He tried this with good effect, the supposition being that the weight of the gypsum kept the soil more compact and prevented the throwing out of the plants. What think you? (b.)

I suppose, of course, that thorough drainage would operate as a permanent cure of such soils; but with us, where stones are not to be had, and

tiles are very costly (owing to transportation), the next best plan seems to be the one I have suggested, giving, besides, a coat of manure. (c.)

(a.) Excessive cold is less injurious to winter grain, than the alternate freezing and thawing by which the roots are broken and the plants "thrown out" on wet soils, by the repeated expansions and contractions of the earth around them. Any covering of light material capable of holding considerable air, as snow, straw, leaves, etc., serves as a regulator of the temperature. Thus, on a warm day the air contained in the mulch being a poor conductor of heat, will partially prevent the soil beneath it from thawing, and during the cold nights it will partially retain the warmth gathered during the day, and prevent hard freezing. The mulch may also protect some of the roots from being killed, until they can fasten upon the soil, as suggested by our correspondent, but its chief value is probably due to the facts noted above.

(b.) One-and-a-half bushels of gypsum, sown broadcast over an acre of ground, would have no appreciable effect on the compactness of the soil. In the case mentioned above, the grain was probably stimulated to strong growth by the plaster, and the Winter being very favorable, the yield chanced to be better than ordinary.

(c.) Yes, draining is the cure. Where neither tile nor stone drains are available, wood drains as described in the *June American Agriculturist*, 1861, (Vol. XX, page 169) will usually answer a good purpose, for a few years at least.—Ed.]

A New-Jersey Corn Marker.

P. S. Brokaw, of Somerset County, N. J., writes to the *American Agriculturist* as follows: I propose offering your Iowa correspondent (C. J. Rhodes, in Jan. No., p. 15) a New-Year's present, in the form of an improvement on his corn marker. When about dispensing with the common plow in marking for corn, some years ago, we tried his plan among other things; but by perseverance in experimenting, we have found the common block sled, with the improvement represented in the annexed sketch, far superior. 1st. It is much lighter, and requires less room in housing; 2nd. there is no need of stakes, set up in the field as guides, especially if

there are two straight sides to the field; 3d. the marks will all be of uniform width, which is of great importance in the after cultivation of the crop by horse power. In making the implement, the runners, *r, r*, are, of course, set as far apart, as the rows of corn are intended to be. To the middle of one of the beams, *b*, a guide-pole, *p*, is attached, so as to admit of its being swung over to operate on either side of the sled. This pole is made twice the length of the distance between the runners: thus, if the rows are to be four feet apart, the guide-pole must be

eight feet long. On the outward end of the guide-pole, a shoulder is cut, to enter a hole in the block, *m*, which is to serve as a marker. The block turns on the pole, when the latter is changed from one side to the other of the sled. A stout pin is set in the lower end of the block, at right angles with it, to make a distinct mark on the surface of the ground. Two pins are also placed in the top of the runners, to keep the guide-pole in place, when in use.

In operating with the marker, the driver takes his place upon the sled, and marks the first two rows by following guide stakes, or the line of the fence. The guide-pole being swung over on the side of the unmarked land, the marker traces a line in the center of the space between the next two rows, and on reaching the end of the field, the horses are turned, the guide-pole reversed, and the team is driven so as to keep the guide-line exactly between the horses, and thus the rows are made parallel with those previously marked.

Winter Management of Sheep.

The old practice of leaving sheep to shift for themselves whenever the ground was bare, is now abandoned by all good flock masters. It is not denied that they can gather a good deal of nourishment from the meadows, if they have not been picked too bare, but the grass is of poor quality, frost bitten, and is insufficient in quantity. It interferes with the regular habits of feeding the flock, which is a matter of some importance with the shepherd, and a good deal more with the flock. After they are once yarded in the beginning of Winter, it is better to keep them in confinement, unless it be for a run of an hour or so, on very pleasant days.

Sheep want shelter from the storms and protection from bleak winds, and no man should attempt to keep them in the Northern States, unless he can furnish covers for them. These need not be expensive. The instinct of the sheep prompts it to seek high, dry lands, especially for lodging, and such a locality should be selected for the barn. They want protection from the snow and rain more than from cold. They will bear a very low temperature without inconvenience, if their fleeces be dry. A barn-cellar in the side of a gravelly hill, with a yard attached, is a very good arrangement for them. If this is not upon the premises, cheap sheds may be built with board or thatch roof. The shed should be deep and open toward the south. It will not be expedient to confine more than fifty in a single shed and yard; and if the flock be not uniformly vigorous, it will be better to reduce the number to twenty five, assorting them according to size and vigor, so that all may have an equal chance at the fodder. If this matter be overlooked, the stronger animals will push away the weaker, and take the choicest portion of the food.

The barn-cellar, or shed, should have a good layer of muck or loam at the beginning of the feeding season, and should be kept well littered with straw or refuse hay; then the manure will not become prejudicial to health, and may remain until they are turned out to grass. The sheds should be furnished with convenient racks for feeding hay, grain, and roots. The sheep demands a greater variety of food than any other domestic animal. It is said that Linnæus, the distinguished botanist, offered a variety of fresh plants in succession in feeding horses, and found that they ate 276 species and refused 212; cattle ate 276 species and refused 218; while sheep took 387 species, and refused only 141.

This shows that a good many plants that are rejected by other animals, may be turned to profitable account in sheep feeding. We may save the small shrubs and weeds and coarse grasses which are often burned in clearing brush pastures, always taking care that the poisonous Low Laurel be not gathered with the fodder. We can safely feed them once a day with this coarse fodder, and it is perhaps better that it be given at night. In the morning they should have nice short hay, the best the farm produces, and all that they will eat up clean, and no more. The same rule is good for the noon-day meal, which should be of roots or grain. The grain should be given whole, as sheep are furnished with good masticators, doing their work as perfectly as any mill. Nearly all the grains and their straw may be fed, changing occasionally from one to the other. Turnips, beets, carrots and potatoes are excellent food for sheep. It is a matter of a good deal of importance that they be fed regularly. No animal knows better the appointed hour of feeding, or is more impatient under disappointment. The stomach must be kept quiet by regular feeding, if we wish the flock to thrive. They should also have the same amount of nutriment every day, as nearly as it can be calculated. Each animal wants about three per cent. of its live weight in food, a little more if fed upon hay and roots, exclusively. If a sheep weigh a hundred pounds, it should have, say half a pound of corn or an equivalent in other grain, a pound of good hay, and two pounds of straw, the three being nearly equivalent to three pounds of good hay. A little observation will soon fix the quantity needed, and prevent over or under feeding, both serious errors. Water should be carefully supplied to the flock, and if it is spring water that never freezes, brought in a pipe to a trough in the yard, it is all the better. If a sheep falls off in flesh or grows weak, it should be immediately removed where it can have a full supply of food, without struggling with stronger animals. Salt should always be kept in the yard, where sheep can have free access to it. By attention to these small matters at this season, the flocks will be kept in good health and come out robust in the Spring, with full fleeces.

Lustre Woolled Sheep—The Lincolnshires.

The term lustre wool, is applied to fleeces of long staple, possessing a bright or lustrous appearance. The Cotswold and Leicester breeds are the best known of this class, in this country. The wool is in large demand, particularly for the manufacture of what are termed alpaca fabrics. These derived their name originally from the animal (alpaca) producing the silky hair, that gives a lustrous appearance to the goods. The fitness of lustre wool for the above purpose, gives it a value above what it would possess, if graded only by the standard of fineness, and it is worthy the attention of sheep breeders to inquire whether coarse-wooled sheep of this class may not bring a better profit than the favorite Merino and Saxony breeds, or even the middle-wooled South Downs. The latter breed is rapidly and deservedly becoming popular, particularly for supplying superior mutton; but some of the coarser wooled varieties may be equally profitable by greater weight of carcass. In England, considerable attention is being attracted to the Lincolnshire breed, for which their advocates make special claims as lustre-wooled sheep. A recent writer in the *Mark Lane Express*, gives figures which will in-

terest sheep-breeders. He states that the clip of six flocks of Lincolnshire long-wools, numbering 2,389 fleeces, yielded 24,917.66 lbs., or a little over 10½ lbs. per head, which at present prices of wool of that grade would yield nearly \$5 for the fleece of each sheep. These are said to be "good clips," but by no means the best to be met with. As to weight of carcass, extraordinary instances are mentioned, of 261, 284, 364, and 386 lbs. per sheep, of two to three years old, and 50 to 75 lbs. per quarter is said to be common.

The writer of the above statement is of opinion that the Lincolnshires can be successfully introduced, wherever good natural pasturage can be found, and good turnips, or good clover can be produced, but that it is useless to attempt their introduction into mountainous or even very hilly districts. They are particularly suited to rich valleys of those districts not subject to frequent changes of weather.

Due allowance must of course be made for the enthusiasm of one who makes this or any particular breed of animals a hobby, but the facts set forth are worthy of consideration. We are not aware that the Lincolnshires have been tried to any extent in this country. If any readers of the *American Agriculturist* have experimented with them, we should be pleased to have their notes for the benefit of the community. *

For the *American Agriculturist*.

Improvement of Pastures.

The condition of the pastures in many of the older dairying districts is a sad spectacle. Farms that would once carry forty cows, and make eight thousand pounds of butter, will not now support half that number. In the familiar language of these districts, the land has been "cowed to death." The pastures have been fed by cows from time immemorial, receiving only the manure dropped by the animals during the day. Three fourths of all that the land produced was carried away to the yard, and none of this came back. The soil grew thin, and the grasses died out for want of nourishment. What can be done to bring up such pastures?

An ounce of practice is said to be worth a pound of theory. It is, undoubtedly, if of the right kind. In the Spring of 1860 the writer came into possession of a two acre lot of run-down meadow. It was used as a pasture because there was not grass enough upon it to pay for cutting. As it was convenient to the house, I used it for yarding the cows at night. They were pastured elsewhere a part of the time, and thus all the products of these two acres, and nearly four more beside, were dropped upon the soil by the cattle. There has been a very great improvement in the yield of grass the past season, and the lot, if used for meadow another year, will probably cut twice as much hay as it did in the Summer of 1860. The whole secret of the improvement is, that more has been returned to the soil than has been taken away.

A similar improvement is witnessed in pastures devoted to sheep, if they are not fed too closely. Every thing the land produces is returned to it by the sheep, together with a good deal the land would not get, but for the intervention of the feeding animals. It is sometimes claimed that nothing is gained to the land by passing the crops through the bodies of animals; that a hundred pounds of hay rotted upon the land, is worth just as much as the hundred pounds fed out and returned in the shape of manure. But this can not be so, for the animal draws some elements of its body from air and water, as well

as hay, while the manure quickens the energies of the soil, as the rotted hay would not.

It is well known in the districts devoted to the feeding of fat cattle, on the ridges of Dutchess and Putnam counties, and the western part of Connecticut, that lands once poor, or nearly run out by hard cropping or pasturing, have been brought up to very great fertility, by plaster and feeding animals. From one to two bushels of plaster per acre are sown every year, and fattening cattle three years old and upward are kept in them from Spring until Fall. When the animals are turned in they have their frames already made, and there is no great draft upon the soil for bone earth. The whole grass is returned to the soil in the manure, except the little carried off in the gain of the cattle. Some times a change of stock from cows to fattening bullocks, or to sheep, will be all that is necessary for improving a worn out pasture. If cows are kept, there must be top-dressing, or alternation from pasture to hoed crops, with heavy manuring. If the land is not arable, top-dressing with compost or with plaster in districts where it does good, will be sufficient. CONNECTICUT.

Manuring or Mulching.

There is much to be said in favor of top-dressing grass-lands in the Fall with coarse manure. It protects the roots from the severity of frost, also from the cold drying winds, which often prevail when the land is bare of snow. Meadows so protected come out in the Spring earlier, brighter and stronger. This no one will deny. But is this result owing chiefly or altogether to the action of the manure as a fertilizer? Doubtless some of it finds its way to the roots in liquid form, but not much in Winter. The benefit comes largely from its action as a protecting mulch. And if so, the question arises whether this is good economy, at least where the land is poor and manure so expensive as it is at the East. When practicable, why not dress the grass-lands with a thin coat of straw, leaves, or sea-weed? Meanwhile, let the manure be carefully housed under sheds near the barn, where it will be improving all Winter, and be in a perfect state for application in Spring. Perhaps some of our progressive farmers will try the experiment, on a small scale. Mulch one piece of sward this Fall with straw, and another with manure. In the Spring see which looks best. Give both the same amount of manure in the spring-plowing, and see which yields the best crops. The subject is an interesting and practical one.

Farm Notes from Minnesota.

H. A. Farmer of Goodhue Co. gives to the *American Agriculturist* some notes on farming in Minnesota, from which we extract the following: Having to stack a part of his corn, he adopted the following expedient for loading and unloading shocks: "I had thirteen ropes, used for tying cattle; one of these I would slip-noose around a shock, draw it up snug, pass the end of the rope to the man on the load, and then, with a vigorous toss and pull, land on to the wagon a shock, that would turn out a bushel and a half to two bushels of ears, leaving the rope on every shock—thirteen making a load. To unload, drive to the end of the rick, run a wide plank to the wagon rack, take hold of the rope, shoulder arms, and walk the plank."

The following is his method of manuring his

straw stack: "I keep thirty head of cattle, young and old, and my straw is quite an item for their winter forage, but I dislike to force them to eat it. I had thirty-seven acres of wheat handy to the cattle yard, which I drew up and stacked in two stacks, and while topping out, I sprinkled salt over every layer of bundles. When it was threshed, of course, the salted straw was at the bottom of the straw stack. The result was, that my stock ate the straw with avidity, and made themselves very comfortable sheds about the straw stack. The salt made no difference with the grain."

For the American Agriculturist.

How Much Pork in a Bushel of Corn?

It is important that hog raisers should know how many pounds of pork can be made out of a bushel of corn, that they may decide whether it will pay best to sell their corn or feed it to hogs, at the existing prices of each. I have been making some experiments and taking some notes which may interest many of your western readers, as it would interest me to see similar notes of plans and results of others.

On the 13th of September last I had on hand 120 head of hogs, various sizes, from sucking pigs up to 250 lb. hogs. The lot weighed 8,500 lbs., and all run together in an 8 acre lot, about 6 acres of which is set with white clover and blue grass. I fed them from September 13th to December 1st, 660 bushels of corn, by throwing it to them dry on the ground, together with all the stove coal ashes and salt they would eat, (the coal was fed to neutralize any acid in the stomach, caused by high feeding, and prevent cholera or other diseases.) They were furnished a dry place to sleep in. On the first of December I sold 7,806 lbs. of fat hogs, and found the entire lot had gained 9,702 lbs., or 14.7 lbs. for each bushel of corn fed. They are mostly a cross between the Berkshire and Suffolk, with the Berkshire predominating; some few have a cross of the Chester White.

HOG RAISER.

Ridge Farm, Illinois.

Notes on Flax Culture.

The numerous inquiries upon the subject of flax culture received at the *Agriculturist* office, from different sections, show that the attention of many cultivators is already turned to this crop, which at present promises to be a remunerative one for the coming year at least. The following information derived from many sources will be of value to those inexperienced in growing flax, and we trust that any difference of treatment called for by peculiar circumstances of location and soil, and additional suggestions from those experienced in the business may be communicated in time to be of use to our readers before putting in the spring crops.

Flax prefers a rich sandy soil, but grows well upon any land that will yield good corn. A fine deep tilth of rich soil with good draining will give the best crops. It is almost useless to attempt the cultivation of this plant on a wet field. It is essential that the ground be free from weeds. In Europe, where labor is cheap, the flax fields are regularly weeded; here, the process would be too expensive, and hence the cleanest land should be selected. Flax may well follow corn or oats, or be sown directly upon a clover sod. In the latter case especially, it would be better to plow the land the previous Autumn, leaving it in ridges, to allow the vegetable matter to decay, and be more thoroughly

mingled with the soil by reploting and harrowing in Spring. Heavy manuring is beneficial in increasing the yield of seed, but it makes the fiber coarser and less valuable. Flax will doubtless do well after any previous culture that has left the land "in good heart" and free from any troublesome weeds.

The quantity of seed per acre varies with the purpose of cultivation. If the object be to secure seed only, three pecks per acre is ample. When sown thus thinly the stalks throw out more branches, and a larger quantity of seed is produced. Where the crop is grown for the fiber alone, from one and a half to two bushels per acre is used, according to the strength of the land. In some districts of Europe where the finest linens are produced, as high as three bushels per acre are sown. It will probably pay best to sow with reference to raising both seed and fiber; then one bushel, or on strong land, five pecks per acre will be the proper quantity. The seed may be obtained at almost any city seed store. That of good quality will be smooth, slippery, and will sink in water. It should taste sweet when chewed, and being broken, should appear of a light yellowish green color, and very oily. If large quantities are required, it would be well to correspond with those in the trade at Cincinnati or St. Louis, which are commercial centers of the large flax growing districts, where the seed is chiefly the object of culture.

The time of sowing, of course, varies with the latitude; the rule is to get in the crop as early as can be done without danger from frost. In Rensselaer and Washington Co.'s, in N. Y. State, about latitude 43°, where large quantities are cultivated annually, it is usually sown from May 1st to 10th. The seed is thrown broadcast, and it requires considerable care to scatter it evenly. Calm weather should be chosen for the work, or if that be not possible, the sower should always work with the wind at his side, blowing alternately on his left hand and on his right as he paces up and down the field. A more uniform distribution of seed could be secured by going over the ground twice, and sowing half the amount of seed each time. The quicker the flax germinates and appears above ground, the better the crop is likely to turn out. On this account, it is a great advantage when the sowing can be done immediately before a shower. If there be drouth at the proper time for putting in seed, its effects can be partially guarded against by a deep thorough harrowing immediately before sowing. The seed is to be harrowed in lightly, and the use of the roller after this last harrowing will be beneficial especially on light soils. Details as to harvesting and subsequent treatment of the crop, will be given in a future number.

We will add a few items in answer to those asking special information on the subject: The average yield of an acre of good land is a ton of rotted flax, and from ten to twelve bushels of seed. A ton of rotted flax properly treated, will give from 450 to 500 lbs. of dressed flax, about 70 lbs. of coarse tow, and 12 to 15 lbs. fine tow. It would not pay to transport flax in the straw to any great distance; if properly broken, some 60 per cent. of the woody part may be separated, and then it can be profitably baled and sent to market. The brake for this work described in the January *Agriculturist*, (p. 12), can be as readily moved from one neighborhood to another as the ordinary threshing machine, thus enabling the farmers of a large district to prepare their straw for transportation.

American Jute.

At the present time there is great interest in every plant which promises to be available for fiber. In the January *Agriculturist* a brief notice was given of the American Jute: which has called out numerous queries as to the appearance of the plant which furnishes it; we give an engraving of the flower, leaf and seed vessel. This sketch, which is about half the natural size, will enable anyone to recognize it among our wild plants. The flower is generally rose-colored, but is sometimes white, with a crimson centre. The lower leaves are more irregular in outline than those represented in the engraving, and all are covered on the lowerside with a light-colored, velvety down. The plant varies somewhat in different localities, and it was formerly supposed that there were two species, which were named *Hibiscus Moscheutos*, and *Hibiscus palustris*; but they prove to be the same plant growing under different circumstances, one on the sea-shore and the other inland, and the former name (*H. Moscheutos*) is retained.

Though the plant grows most abundantly in the neighborhood of salt water, it is not very rare in the interior. It will probably grow almost anywhere, but will doubtless flourish best in low grounds. We have for several years cultivated it for ornament, in a very sandy spot, where it grew with great vigor. The plant may be raised from seed, or by dividing the large clumps of roots. All our knowledge of its alleged value as a fiber producing plant is obtained from the statement of the patentee employing it for that use. We only notice it as one of the articles now claiming a share of public attention.

Flax Cotton.

An interesting sample of batting made from flax has been placed on the *Agriculturist* Exhibition tables. It is intended for quilting dresses, comforters, and such other purposes as cotton batting is employed for. The specimen was made at a factory in Lockport, N. Y., which is the center of a large flax raising district. The flax straw is first pressed through a brake, the invention of Stephen Randall, of Rhode Island, which consists of a series of fluted rollers so geared that they run at different speeds, thus producing a motion by which the fiber is freed from the woody portion. After passing through

a duster, which further cleans it, the fiber, if required white, is bleached, dried and carded. In making yarn or twine, suitable machinery, similar to that used in the manufacture of cotton, is employed. It is the intention of the company to supply an article which may be mixed with wool or cotton in fabrics, to make twine, crash, bags, railroad car backing, and similar goods.

About the Weather.

The remark is often made, that this or that month has been unusually cold or warm. A few very hot or cold days are apt to give the impression, that the month or season has been very different from the average, with respect to temperature. But the same month through a series of years shows a great uniformity of temperature, and the years, taken one with the other, vary but little. The following table of observations, taken by Mr. H. T. Haviland, at Brooklyn, N. Y., gives a striking illustration of this. Here, but one observation each day is made use of—from May 1st to Nov. 1st at 6 A. M.; and from Nov. 1st to May 1st, at 7 A. M. It will be seen here, that the average of January and July together, give very nearly the average of the year; and so with the other opposite months. It must be borne in mind, that the average of 47° is not the mean of the year, but only that of the morning observation. Observations taken in New-York city six times a day, during nine years, gave never less than 53°, nor over 55°, as the average temperature of each year:

Valuable Record, for Farmers and Others.

The accompanying diagram shows a simple and very satisfactory plan for keeping a record of matters which are subject to variation—as, for instance: the height of the thermometer, the rise and fall in price of grain or other products, the amount of yearly produce on the farm, etc. It has long been in use among scientific men,

but is so admirably adapted for operations on the farm and elsewhere, that thousands of the readers of the *American Agriculturist* will be interested in examining its working, and in making it useful in their own business matters.

Our illustration was prepared some time since, to exhibit the method as actually used in our office, for noting the changes in the barometer; but in a recent number of the *London Gardeners' Chronicle*, a similar plan is shown, for exhibiting the increase and decrease of the flow of milk in a number of cows, and that being a matter of very general interest, we will illustrate the working of the record so applied.

The numbers at the top of the diagram designate the days of the month, to each of which is assigned one of the spaces made by the perpendicular lines. The figures at the sides, 1, 5, 10, etc., stand for quarts of milk, each space between the horizontal lines representing one quart. The daily yield of milk by each cow is shown by the irregular lines, running from left to right. Thus: it appears by the above record, that on the 1st day of the month, one cow (a) gave 8 quarts, and the other (b) 11½ quarts. On the 2d day there was an increase in each, a, yielding 9½ qts., b, 12 qts. The increase continued with a, until it reached 14½ qts., on the 8th of the month, when there was a slight decline for a few days, after which the amount rose to over 19 qts., on the 17th day, and then rapidly fell away. Now, if notes were made in the perpendicular spaces under the dates, of the different kinds of feed given, change of pasture, and other circumstances supposed to affect the flow of milk, a glance at the record would determine whether the change were favorable or otherwise. The cases noted above are imaginary ones, but they serve to fully illustrate the method. The horizontal spaces can also denote degrees for the thermometer or barometer, bushels for grain, cents for the price of commodities, or any other denomination required; and the number of spaces can be altered to suit any business or other matter. The perpendicular spaces can also be used to represent as many weeks, months or years as are desired. Where several records, liable to become confused, are marked on one sheet, they can be kept distinct by using different colored pencils or ink, or by making dotted, or broken lines.

As remarked above, the changes of the barometer are recorded in this manner at our office, and it perfectly demonstrates the usefulness of the plan, to notice how exactly the rise and fall of the mercury correspond with the variations in the atmosphere. Where the indicating line rises, the accompanying notes read: "Fine weather," where it falls, there is recorded: "Cloudy, rain, snow, or wind," etc. A few years of such records, pertaining to various farming operations, would be invaluable as ex-

hibiting the success or failure of different methods of treatment. They would be like charts, pointing out paths to be followed, and rocks to be avoided. Whatever appeals directly to the eye, produces a stronger impression than any written statement can do. One who, upon consulting his chart, should find his lines continually running down hill, would be strongly incited to a change of his present management.

For the American Agriculturist.

Cheap and Convenient Barns for New Countries.

Where durable timber can be procured, such as locust or cedar, cut posts four feet longer than the height desired for the barn; frame a tie on the tops of each four posts; let the tie project eight inches beyond each outside post, (i.e., let the ties be one foot and 4 inches longer than the width of the barn). On top of the ties cut in a boxing or groove, $1\frac{1}{2}$ to 2 inches deep, for the plate to rest in. Now sink holes in the earth, three or three and-a-half feet deep, bringing the bottoms of the holes all to the same level; which holes are to receive the lower ends of the posts. Raise the bents one by one, tamping the earth firmly around the posts as the holes are filled up; pin the plates to the top of the ties; and finish the roof as for a frame barn. For side covering, take 2x4 inch scantling, and spike them on the posts firmly, with 6 inch spikes, as far apart as is desirable, (say 4 feet), and nail the siding to them. If the two end ties and the two plates are allowed to project two inches over the posts, outside, it will save scantling in those places. For the floor foundation, lay down three or four pieces of hewn timber across the width of the floor-way; on top of these lay a sufficient number of hewn timbers lengthwise of the floorway; and lay the flooring plank across them. A piece of timber framed in the posts just under the plates, and over the floorway, will receive and hold fast the top end of the posts to which the doors are hung, while the lower ends are mortised in the floor foundation. Hang the doors and the barn is finished. Though so little of a carpenter that I do not know the names of the timbers to a barn, I have just erected one, without aid from a carpenter.—In this connection I would suggest a plan for a convenient and economical barn, for a large farm, viz.: 40 by 64 feet, divided into four bays, each 16 ft. wide, by 40 ft. long. Make threshing floors, and hang doors, to the two middle bays (b, c).

Drive on one floor (b,) and unload the hay or grain in one bay (a) at the end of the barn: close the doors to that floor, and drive the loads on the other floor (c); fill up the other bay (d), and the floor first used (b), and still there is a threshing floor (c) for use. A stable can be made in the bay (d) at the end of the barn next the unfilled floor, and by building the same floor a little higher from the ground, a convenient cellar for roots, can be constructed. I have seen

thousands of barns, but have never seen any which economize space like one on this plan. Such a barn, built with posts set in the earth, would require 20 posts; which planted $3\frac{1}{2}$ feet deep, with the soil well rammed down, would withstand any wind, without braces; for there would be 20 trees (posts) to be upturned. *Seattle, Washington Territory.* ECONOMY.

Farm Gates.

Among all the improvements which have been made in farm conveniences, there is still a lack of a simple, cheap gate; one which will be sufficiently strong to stand constant and rough usage, and yet not so heavy as to sag. Nothing is more annoying than to be obliged to carry half the weight of the gate in the hands, every time it is required to be opened or closed.

Isaac P. Allen, Whiteside county, Ill., sends us a plan of a gate, which he claims is free from the usual objections. It is certainly very simple, and can readily be made by one of slight mechanical skill. The head piece, A, is made of 4 inch scantling. The brace, B, and the bars are mortised into this and secured by pins or bolts. The heel piece, C, is made of two pieces of inch boards, fastened one on each side of the cross bars. The latch D, is a simple bar of hard wood, sliding on the cross bar and between the boards of the tail piece, and kept in place by the strip placed at E. The latch is kept closed by means of a hickory spring F, which is fastened by staples to the latch, and to the gate; the end of this spring projects above the latch and serves as a handle by which to draw it back. To hang the gate, pins of $\frac{3}{4}$ inch iron are placed in each end of the head piece, and irons G and H, with a hole punched in the end to receive the pins, are fixed in the gate post. These are fastened by an iron wedge driven in by the side, or what would be better, may have a nut fitted so that they may be secured in place. The catch is represented at I; it should be made of hard wood, and be bolted to the post at the proper height to receive the latch. This will allow the gate to be opened both ways. There are now several weeks in which much can be done in making gates and similar work. They should be made of hard wood and well seasoned, the mortises put together with a tight fit, and every tenon thoroughly pinned or

bolted. The slats and brace may be $\frac{3}{4}$ of an inch thick and 4 inches wide. The posts should be well seasoned, with all the sap-wood cut off and the portion which enters the ground well charred. They should be set at least 3, and better 4 feet in the ground, with the earth well pounded in to hold them firm.

Brush-harrowing Potatoes.

Mr. Jonas Weed, of Fairfield Co., Conn., writes to the *American Agriculturist*, that much time and labor may be saved, and weeds effectually destroyed in potato culture, on dry, light soils, by turning furrows from both sides upon the rows when the potatoes first appear, following immediately with a brush harrow, which he constructs as follows: In a stick of timber about 4 inches square, and 8 or 9 feet in length, he bores 2-inch holes 18 inches apart, and fastens the butt ends of tough saplings, or brush, in these holes. The timber follows the team at right angles, the brush projecting behind it. The draft should be attached to the underside of the timber, so as partially to raise it from the ground and throw its weight upon the brush. The covering of dirt kills the weeds, while the potatoes are not injured by it. Mr. J. further says that an implement made in the same manner, with the exception of substituting a plank, instead of the timber, so arranged as to incline forward, is excellent for preparing for clover, and other fine-seeded crops.

Implement for Cutting Hay.

An unknown correspondent, modestly signing himself "J. C. M.," sends us a neat model of the implement illustrated below, of which he writes: "It has long been in use in England and in some parts of this country, and is so much superior to the common hay-knife that it ought to take its place. It is called the Hay Spade. It is made of steel plate about $\frac{3}{4}$ of an inch thick, or less, cut in the form here represented, and thinned from the middle to each side until the edges are sharp. When finished it measures about 10x14 inches, more or less, as desired. The socket for the handle is bent slightly forward, to prevent rubbing the back of the hands against the hay when cutting. The handle is of wood, about 2 or 2½ feet long, made wide at the end for the socket, and about the size of a stout fork handle at the upper part, with a piece the same thickness about five inches long, across the top. The handle is fastened in its place by a screw nail from the back of the socket. I would not give mine for a cart load of the common kind, if I could not replace it with another; it saves time, hay, and labor, is cheap, strong, durable. One will last a lifetime if used with care."

SPLITTING WOOD.—S. Parsons, says, the boys engaged in splitting the year's fuel, can make it easier, and lessen the danger of cutting their feet by the following arrangement: Take a large block of hard wood, say two feet or more in diameter, and of convenient length; set it up endwise, and in the middle dig out a hole seven or eight inches in diameter, and about six inches deep. This will hold the sticks upright, and they can be split into several pieces without handling. The hole can be easily made in a very little time with an auger and chisel.

Sorghum Culture.

The importance which is attached to Sorghum, especially at the West, is shown by the holding of two Conventions of those engaged in cultivating the plant, and manufacturing its products. The one held at Rockford, Ill., Dec. 3, was attended by over 150 practical men, whose experience on various points, as elicited in the discussions, will doubtless be of value to the country at large. The subjects proposed for discussion were: 1st. Best seed and its preparation; 2nd. Best soil and its preparation; 3d. Mode of cultivation; 4th. Machinery for working up the cane and preparing its juice. The discussion upon the first topic shows that great difficulty is experienced in procuring good seed, and that this is liable to deteriorate. The following is the report of the committee on seed, which was adopted by the convention.

REPORT OF THE COMMITTEE ON SEED.

Your committee, to which was referred the subject of seed, beg leave to report, that in consequence of the great diversity of opinions and experience of different producers, they find it difficult to designate any one variety of cane to be preferred to all others. It appears from accounts given by various members of the convention, that any one of the canes grown in the country, when raised from the pure seed, with proper culture and care, produces good results. In the selection of seed, therefore, special regard should be had to the question of its purity or freedom from amalgamation with other plants which tend to its deterioration. The production from the yellow Imphee, or African cane, has more frequently resulted in crystallization, than any other. This variety is also desirable on account of its habit of early maturing. Of the different kinds of Chinese cane known in this country, the committee infer from all the information before them, that neither the smallest, earliest varieties, nor yet the largest and later sorts, but a medium between these two extremes—the committee know not by what name to designate it—is most desirable for cultivation. As a means of success in the business, the committee urge careful observation on the part of all growers, and recommend the selection of such crops as the experience of producers has proved most profitable, always guarding with the most scrupulous care against every appearance of mixture with all and any of the plants, with which the cane will hybridize.

The committee would also recommend the importation of seed from time to time, from localities where the climate is more congenial to the perfection of the cane, peradventure the deterioration in its quality, sometimes noticeable, may thereby be obviated. All of which is respectfully submitted.

C. A. HUNTINGTON, } Committee.
E. H. SEWARD, }

Mr. Murtfeldt offered the following resolution:

Seeing there are so many names given to the different kinds of cane, according to color of seed, or any other peculiarity, in order to secure a more uniform designation, I offer the following:

Resolved, That in the estimation of this Convention there are only three kinds of cane, viz.: Chinese Sugar Cane, having black seeds, growing in prongs from 2 to 7 inches long; the second or tufted variety to be known as African; the third, lately introduced, to be known as the Otaheitan, having long heads, 7 to 12 inches long, and 1 to 2 inches thick.

The uncertainty with regard to seed appears to be one of the greatest difficulties of the cultivator, and it is doubtful if sending, as some propose, to more southern localities, will permanently better the matter. What is needed, is a variety suited to a northern latitude, which will maintain itself year after year. The Sorghum is, like the Indian corn, liable to great variation, and a permanent variety, or race, can only be established by careful selection and cultivation. The fact, that one cultivator raised

twelve varieties from one kind of seed, shows the want of stability in the varieties. There is no doubt that by cultivating for the seed alone, and carefully rejecting that from inferior plants; a variety may be established, which will be superior to any now in cultivation. There is needed careful observation as to what relation, if any, the saccharine quality of the cane bears to the color and marking of the seed, and the form of the heads. Whoever will conduct a series of experiments with a view to improving the Sorghum, will do much to remove the uncertainty attending its culture. The opinion of the members of the convention upon the preparation of the seed, was divided, some preferring to plant it dry, and others soaking and sprouting previous to sowing. Mr. Pardee found it advantageous, to soak the seed 24 to 30 hours in a solution of "chloride of lime and vitriol" (proportions not stated,) he then puts it in bags, and covers in warm ground, until it sprouts.

With regard to soil, nothing especially new was brought forward, the prevailing opinion was that any soil being suitable for Indian corn, would do for Sorghum. Manuring, and deep plowing in the Fall, were generally advocated, and a number of speakers gave their experience in favor of ridging the ground, by throwing two furrows together, and planting on the ridges.

Inquiries for Sorghum Seed.

We are sorry to be unable to respond to a multitude of inquiries as to where pure seed can be obtained in quantity for next year. We made diligent efforts to get a lot from France for distribution last Spring, but found that there was the same deterioration there as here, owing to similar carelessness in keeping it free from hybridization. Learning that Messrs. Vilmorin, Andrieux & Co. had sent to China for new seed, we called upon them while in Paris last Summer, to try and secure some; but they informed us that they would probably be able to procure only a small quantity, and that they should most likely propagate all they did get, so as to obtain a supply for the season of 1864. They kindly promised, however, that if they could possibly spare even a small quantity, they would send it to us—but held out little encouragement. We shall be glad for any reliable information as to where pure seed may be obtained, as there is now a great call for it.

The publisher of the *Agriculturist* feels no little gratification at the result of his efforts a few years ago, when he scattered freely over the country tens of thousands of parcels of sorghum seed. Though we charged nothing for the seed except the postage, and advised a trial of but a small quantity at first, yet not a few contemporaries cried out "humbug." This same seed laid the foundation for the immense crop of sweetening grown at the West the past year. Probably three-fourths or more of all the sorghum grown in our country as yet, has come from the seed originally sent out from this office.

GOOD FOR THE NEW-HAMPSHIRE GIRLS.—In Rockingham County, N. H., an aged farmer has sent three sons to the war, leaving himself short of help. Fourteen of the young women of that place recently collected together and husked a hundred bushels of corn for him. Their "lily hands" may have been roughened by the work, but the good hearts going with such hands, will be a treasure to the fortunate winners, worth far more than delicate fingers.

Blinks from a Lantern....XXXII.

DIOGENES VISITS RICHARD BULLION ESQ.

"It is capital that makes good farming," said Mr. Bullion, as he bowed me into his parlor, and pointed me to such a seat of silky, downy softness, as Diogenes rarely sees in all his visits. "With capital," continued Bullion, in that self-satisfied air which he assumes when he remembers that he is worth a hundred and fifty thousand dollars, "a man can make the land do pretty much as he pleases. He has only to tickle the soil with a hoe, to make it laugh with such a harvest as the barns can hardly hold."

Bullion has never seen better days, has never enjoyed himself so entirely as he now does. He has run his race in the city, has got money enough to satisfy a man of his reasonable tastes, and has retired to the country to enjoy the evening of his days—a pretty long evening it may be, for he is now but just turned of fifty. He was a farmer's boy, but precious little good did his birthplace do him, for he left it for a country store at fourteen, strongly bent on merchandise and a fortune. Though he never acquired any skill in husbandry beyond learning to milk, churn, pick stones, and ride on horseback, he learned to love country life, and always cherished the dream of returning to the paternal acres to fix up the old homestead, to keep fat cattle, sheep, and pigs, to drive a good horse, and take premiums at the County and State Agricultural Fairs. It is not improbable that he might have made a farmer, if his father had been a good one. But he managed every thing upon "the penny wise and pound foolish" principle, worked hard himself, and never had half help enough to make his farming profitable. Every thing was done on a small, mean scale, and young Bullion left home early with the parental consent, determined that when he got ready to farm it, he would not be cramped. He succeeded in the city, so far as the making of money was concerned, but never took that social position which his wife coveted for her family. She longed to be invited to Mrs. Gingerwell's parties, in the Fifth Avenue, but never quite accomplished it. She got invited into the Second Avenue frequently, and lived in the Ninth herself. For her part, she could never see why folks who lived in the Fifth Avenue, should feel so much above people who lived in still higher Avenues. She left the city without being able to solve the mystery.

But Bullion did not share his wife's sympathies in this respect. He did not care a snap for Mrs. Gingerwell's parties, so long as old Gingerwell bought his groceries of him and paid his bills. He felt as well in the purchase and sale of tea, coffee, wines, and sugars, as Mrs. Gingerwell did in the use of them, and the aristocratic notions of his customers never troubled him. Richard Bullion was not going to bother his head about such women's notions. Not he!

Well, Richard had realized his dream, at least in part, had got back to the old homestead, had reared a handsome monument to his parents in

the grave-yard, and another to himself on the site of the old house, the first done in marble, and the other in Granite. This granite house is a good notion, and I wonder people who have the means, do not oftener use it for building. It is a classic material, and suits the esthetic taste. It is very durable if properly put up, and will last a thousand years as well as wood will a hundred. We are having now, in the older parts of the country, the third generation of houses, and the most of those now upon the stage will not long survive their hundred years. Is it not about time that we began to have some permanent houses in this country? The material is abundant in most parts of the land, either granite or limestone, and is easily wrought. In some localities stone would be the cheapest, and when once erected, it is a monument to the builder for a thousand years at least. Some are troubled to find traces of their ancestors who have died only two hundred years back. The grave stones have crumbled, and no one can tell what was carved upon them. But granite will not crumble so readily. It makes a very warm house in Winter, and is much cooler than wood in Summer. Bullion admires his house quite as much as his farm, though it was the farm more particularly that I was invited to visit.

"This is the best house in the county," said Bullion, after he was seated. "It cost me the sum of eleven thousand one hundred and twenty three dollars thirteen cents, all complete. It has thirty rooms in it, and I can entertain all my friends that are disposed to visit me. The carpets cost me five hundred dollars, and the mirrors nearly as much more." The house did not need the self complacent owner's eulogy, for it was very richly furnished, though the furniture was not very tastefully arranged, or selected so as to match. The pictures were tolerable, though the gilt frames cost more than the paintings. They did not hang in a good light; but they were upon the parlor walls, and were the evidences of Mrs. Bullion's social position, which was the main thing she cared for. I do not suppose she ever looked at them five minutes in her life. She had a good deal of sense but not much sentiment.

Richard Bullion Esq., was proud of his farming—and it was this I was particularly expected to admire. "I have raised this year," said he, "200 tons of hay, 1000 bushels of corn, made three tons of pork, five tons of cheese, and have taken premiums on the best swine, and the best cows in the county. The sales from my farm foot up about \$3,300, besides all that has been consumed on the farm."

"Well," said I, "let us look a little at this premium farming. How much corn did you get off of your best acre?"

"Just ninety bushels and three pecks, for I measured it because I entered it for a premium."

"And how much did the corn cost you?"

"Well I can tell pretty near," said Bullion, "I put on plump fifty cords of manure for I meant to get the premium any way, and I dropped about ten dollars' worth of superphosphate in the hill. The manure, I suppose, was worth two dollars on the field. I calculate that the corn fodder was just about a fair offset for the labor of plowing and tilling, and gathering. Well, the corn must have cost about \$1.25 a bushel."

"And what can you buy good corn for in the market?" I asked.

"Corn ranged from 60 to 80 cents last year."

"And do you call that good farming, to raise corn at a cost of forty cents a bushel above what it would bring at the extreme market price?"

That was manifestly putting the matter in a new light, and Bullion scratched his head. I saw abundant evidence in my further conversation with him, that every thing was managed upon the principle of great crops at whatever cost. Now Bullion will unquestionably make a grand farm out of the old homestead, but it will not be done economically. Land in good heart can be so managed as to pay for its own improvement. A farm is a *machine* for making money, that does not wear out if it be skillfully worked. Corn ought to be produced at the market price, pay the raiser a profit, and at the same time leave the soil in better condition. It is not good husbandry to lay out four thousand dollars to secure crops that will sell for only thirty-five hundred. Farmers, in many instances, want more capital, but they want more skill quite as much. Money without skill can raise big crops, build big barns, and fine houses, but money alone does not make good farmers.

Seeds—How Long will they keep Good.

There is no general answer to the question, as seeds of different kinds, collected and preserved with equal care, will vary in the length of time they retain their powers of germination. Some seem to be good after an indefinite period, while others are not to be depended upon after they are a year old. The seeds of some trees will not germinate at all if once allowed to dry, and others will only appear the second year after planting. Works upon horticulture are generally deficient in information upon the raising of seeds and the length of time they may be safely kept. While it is safest to keep them at a uniform temperature just above freezing, there are many which will bear great extremes of heat and cold. Plants have been raised from seeds taken from raspberry jam which must have been exposed to a heat of 220 degrees. When buried in the earth, below the reach of those influences which induce germination, there seems to be no limit to the vitality of some seeds.—Among plants commonly cultivated, the seeds of carrots, onions, parsnips, and salsafy, are not to be relied upon when over a year old. Beets, spinach, lettuce, celery and parsley, will keep 2 or 3 years. Radishes, cabbages and turnips, 4 or 5 years. Melons and cucumbers may be kept for 10 or more years; old seeds of these are preferred by some gardeners, as the vines are said to be more prolific and less luxuriant than those from fresh ones. Good seeds being heavier than water will generally sink in it, but this is not applicable to those with a hairy or spongy seed-coat; such seeds will float even when sound. The only sure test is to try to sprout them in boxes or pots of earth. If they do not germinate there, they should be rejected.

For the American Agriculturist.

Good Winter Butter from Roots.

Every person who has an acre of good land, and good cows, may have butter in January and February, equal, or even superior, to that which is made in September. Though not a farmer, the writer subscribed for the *Agriculturist* in 1860. An article was published, recommending rutabaga or Swedish turnips as food for cows. In the Spring of 1861, seed was obtained, and planted in rows 3 feet apart, and 5 inches distant in the rows. The ground was not the best for roots, yet I obtained from 4 rows, each 100 feet long, roots enough to feed

two cows, once a day, five weeks. The cows had commenced to decrease in the quantity and quality of the milk, after having been taken from the grass, and before feeding the roots, but in a few days there was a marked increase in both respects. The butter was equal in quality to what was made in June, and in quantity to that made in October. It was worth 3 or 4 cents per pound more than the white, oily *substitute*, generally found on farmers' tables at this season of the year, in places where neither roots nor grain are used. Those who have even small plots, would do well to raise roots next year. Begin in time; select good soil, manure during the Winter, and have the ground ready by planting time. The profit on the few bushels raised this year, far exceeds the cost of the paper which led me to make the experiment. K.

Union Cheeses.

A "Union Cheese House" has been for some time in successful operation at Oriskany, Oneida Co., N. Y. The milk from a large neighborhood is collected and converted into cheese by the aid of the best machinery and appliances. The manufacture on an extensive scale by those who make it their sole business is done much more cheaply, and a more uniform product obtained than is possible in the small way. Believing that a similar enterprise would be successful in other localities, we quote an account of this one from the *Utica Morning Herald*:

"The main building is one hundred and seventy-six feet long by about forty feet wide, and two stories high. This is used principally as the drying room, and is furnished with framed tables running the entire length of the building. Upon these tables the cheeses are placed when taken from the 'hoop,' and are turned daily, as in ordinary dairies. Besides this, there is a press room, and vat room, some twenty feet square, each. There are six vats, each holding about 500 gallons, in which the curd is prepared for the hoops. There are nine 'pressure hoops' for 300 lb. cheeses; one for cheeses of 700 to 800 lbs. each; and one for 1,000 pounders. The concern receives and manufactures the milk of nine hundred cows, the most distant being four miles from the factory. As the milk is brought in it is carefully weighed and the owner credited with the number of pounds received.—One cent per pound is charged each customer for his cheese making. In addition to this, the parties furnishing the milk, pay a ratable proportion of the expense of salt, cloth for bandages, and for boxes. The whey is an important consideration. This belongs to the company; it fattens two hundred hogs. Shoats are purchased by the company, when weighing, say one hundred lbs. each, and put into the yards attached to the establishment, in the Spring. They are turned off in early November, weighing three hundred pounds and over.

Hogs are "boarded" (fed) for 12½ cts. per week each, for those who do not desire to have them "live with the family." The swine have a large field in which to take their morning and evening walks, and pursue their amusement of "rooting."

Everything is conducted in the neatest manner, and it does one good to witness the difference between the order and cleanliness of this model institution, and the suspicious and slatternly surroundings of some home dairies. We counted seven cheeses upon the table that weighed *ten hundred and forty pounds each!* and ten, that weighed seven hundred and thirty pounds each. The average weight of the cheeses is two hundred and seventy-five pounds each.—The whole product of the manufactory was sold in November, and brought fourteen cents per pound, except the seven large ones which brought seventeen cents per pound, realizing the sum of forty thousand dollars or over. This sum paid a very handsome dividend to those who patronized the establishment.

"THE COVEY."—FROM A PAINTING BY J. WOLF.

Engraved for the American Agriculturist.

The birds represented in the above beautiful engraving are among the most popular with the sportsman and the epicure. It is counted no small feat to bag a dozen brace of grouse in a day's hunting, especially in settled portions of the country, and enthusiastic gunners frequently travel a hundred miles or more to find the favorite haunts of this game. There are several species of grouse in America, the most common of which are: 1st. Ruffed grouse (*Tetrao umbellus*), called pheasant at the West, and partridge at the East; 2nd. the Pinnated grouse (*Tetrao cupido*), or "prairie hen or chicken." Both of these are sent to city markets in large quantities during the Fall and Winter, and almost always command a ready sale at from 75 cents to \$1 per pair.

The Ruffed grouse is found in every State and Territory of the Union, but is most abundant in the portions North of Maryland. These birds delight in craggy mountain sides, and rocky borders of small streams, among thick growths of evergreens, or tangled underbrush, but will breed in other localities, even among canebrakes. They do not pair permanently, their habits in this respect being like those of the common fowl. In Spring the male attracts the female by the peculiar and well known drumming sound made by beating his wings against his sides with increasing rapidity, until it sounds like a continued roll of distant thunder. After pairing time, the males wander together, apart from the females, until the approach of Winter, when young and old of both sexes congregate in flocks or coveys. The female makes her nest among dried leaves beside a fallen tree, or in the shelter of a low bush. She lays from 5 to 12

eggs of a uniform dull yellowish color. The young follow the mother the moment they leave the egg, and are able to fly several yards when a week old. They are naturally the shyest of birds, and at the slightest cluck of danger, the little ones will hide so as to almost defy detection. They feed upon seeds and berries of all kinds, and when these are scarce, they pick the buds and leaves of several kinds of evergreens. They are very fond of grapes, strawberries and dewberries. They remain near their place of birth the year round, unless compelled to emigrate by scarcity of food. The peculiar whirr made in the flight of grouse only occurs when they are disturbed by the approach of some foe; at other times they pass through the air on the wing as quietly as other birds.

The Pinnated grouse, "Prairie hens or chickens," which are now confined almost wholly to the West, were formerly found throughout the whole North; and a few yet remain in some portions of New-Jersey, on the "plains" of Long-Island, at Martha's Vineyard, Elizabeth Island, and Mt. Desert Island in Maine. Years ago they were so abundant in Kentucky, as to be considered a nuisance, not worth shooting, except to prevent their depredations upon orchards and grain; but civilization has driven them westward with the Indian, and since becoming scarce, they are highly esteemed for the table. Their habits bear a general resemblance to those of the Ruffed grouse, except that they live more in the open country, sheltered by grass. They congregate in flocks in Winter, and in Spring separate into parties of fifty or more. When the love season commences, the males of a flock all resort, early

in the morning, to some particular locality known as the "scratching ground," where they engage in the most desperate battles, a dozen or more at a time often taking part in the general conflict. The victors fly away to enjoy the caresses of their mistresses, the vanquished to console themselves as best they may. During this season the males, instead of drumming, utter a peculiar note, called "tooting." It is made by drawing air into a bladder-like receptacle in the neck, resembling a small orange, and emitting it forcibly at short intervals. The noise is like the beating of a muffled drum, and can be heard at a distance of nearly a mile. Unlike the first mentioned species, the Pinnated grouse are easily domesticated, and raised with as little difficulty as common fowls. Grouse not being insectivorous birds, may be considered fair game; but the indiscriminate slaughter of them at all seasons of the year by roaming gunners, can not be too severely reprehended. They are fit for the table from September to the middle of February or a little later, depending on the season, after which they should be left unmolested to propagate their species. Game laws for their protection exist in some of the States, but from neglect to enforce the penalties for violation, these birds are yearly becoming more scarce.

ECONOMIZING TIME WITH HENS.—C. N. Beament writes to the *American Agriculturist*: "All who are familiar with rearing chickens, know that very few hens will allow newly hatched chickens to be committed to their care. This is probably because the mother hen has become acquainted with her own chickens, from color,

marks, etc., and considers the new comers as intruders, which she too frequently punishes with death. To avoid this, confine the first hen that hatches, in a coop with her chickens, until another brood is hatched; then substitute the second hen for the first, relieving the charge of the former. When a third hen hatches, put her in the place of the second, with all three broods; if the aggregate number does not exceed thirty, a full sized hen will take good care of the whole.

The Measure Worm.

The habits of this pest, which, besides annoying those who travel the streets of our cities, threatens to destroy many of our ornamental trees, have been specially studied by Messrs. H. A. Graef, and Ed. Wiete. They have published, with the sanction of a Committee of the Brooklyn Hort. Society, a pamphlet containing a history of the insect, and a plan for its destruction. Among the trees usually planted in streets, the following are most frequented by the worm—they are named in the order of their liability to attack: *European Linden*, *Silver Leaved Maple*, *Sugar Maple*, *English Elm*, *Horse Chestnut*, *Weeping Willow*, *Silver Leaved Poplar*, *English Ash*, and *Honey Locust*. The trees found to be free from young insects, and only visited by the old ones when other food becomes scarce, are: *Ailanthus*, *Catalpa*, *Cypress*, *European Larch*, *Tulip Tree*, *Paper Mulberry*, *Paulownia*, *Buttonwood*, and *Locust*. The authors propose to save the trees of the infested district in Brooklyn, by a systematic onslaught upon the insect in its various stages, beginning with the eggs, which are deposited on the trunks and branches, and continuing it upon the worm in its various stages of growth. They propose to arrest the worm in its progress from the egg to the twigs by means of tar rings, to syringe with tobacco water to destroy the young ones, and to knock off the old ones by jarring the limbs by means of apparatus for the purpose. Wrens are to be encouraged to build their nests in the trees and lend their aid to the work of extermination. There is no doubt that killing the worm will be sure to save the trees, but whether their plan can be systematically put in operation over large districts will depend upon the public spirit of the inhabitants and their love for shade trees.

To Get Leaders for Evergreens.

It frequently happens that evergreens, of the rare and expensive kinds, are propagated from cuttings or layers from the side-branches of the parent tree. The young plants so raised, are quite slow to form central leading shoots. We have seen such young trees spreading and sprawling about upon the ground for several years, as if they did not know how to rise, having no central spire around which the other

branches clustered, and not worthy the name of tree. This perverse habit can be broken up, and the straggling bush can be forced to throw up a leader. To do this, after the plant has made a vigorous root-growth, peg down all the branches to the ground, as illustrated above. This will so check the flow of sap through them, that a new and vigorous shoot will start up from the base, which will grow erect, and form the nucleus for a new and better tree. After this central shoot has become well established, cut off the old stragglers. Keep the soil well enriched and well tilled for several years.

Farming for Old Age.

Every one with his eyes open has seen many men, farmers and others, make great mistakes in "retiring" early from business. After one has spent the best of his days in active employment, it is quite unnatural for him to suspend all work, fold his hands, and sit down idle. The fancied pleasure flies from him; he was never so miserable before. How much better is it to retire slowly, to give up labor and care by degrees, and never to give them up entirely. Activity, bodily and mental, is necessary to keep one's faculties bright and in a healthy condition. To the farmer especially, we would say, prepare for old age by degrees. If your farm is large, lay off a portion of it for fruit culture. Plant an orchard of the choicest varieties of apples, pears, plums, cherries, and peaches. If a good proportion of the apples are Fall and Winter sorts, they will always be marketable, and will yield a handsome income with only little labor. Plant also a vineyard. The care of it will furnish pleasant occupation for an old gentleman, and the grapes and wine yield considerable income. This point deserves more consideration than it commonly receives. The profits of a farm are never too large, even after the hard labor of one's prime applied to it. But one can not expect to plow and hoe, and hoe and plow forever. Why, then, should we not put our farms into such a condition that when our limbs become stiffened by age, our lands will yield us nearly the same income with less work? That a large and well selected fruit orchard will do this, no intelligent person will deny. A fruit-tree when young costs but a trifle, it occupies but little space, does not exclude hoed crops or grass, and when grown to maturity, yields an annual income of from \$15 to \$40. And besides the orchard and vineyard; let the old man have his garden. In this way, he will have enough to do, and yet not be oppressed with care and labor. Committing the larger part of the farm to his grown-up sons, he can give them the benefit of his experience, while both parties will rejoice in their prosperity and their independence.

Straw Mats—How to Make Them.

Now is the time to make a stock of straw mats, an article useful in every garden. They serve to cover half hardy shrubs during the Winter, are handy to throw over tender plants to shield them from frosts, and where there are hot-beds, they are almost indispensable, to protect them during the cold nights of Spring. They may be made of any size, but it will be found most convenient to have them of a size to cover a single sash. Make a rough frame one foot larger each way than the required mat; lengthwise of this, stretch pieces of large, strong twine, to serve as the *warp*, which may be tied to the frame itself or fastened to pegs placed in

it for the purpose. The pieces of twine should be 8 or 10 inches apart, and the distance between the two outer ones about 6 inches less than the width of the mat. A piece of smaller twine 3 or 4 feet long is to be tied firmly to each thread of warp, close to one end of the frame; these are to serve as *laers* or *binders* to hold the straw in place. The frame being laid flat at a convenient height upon horses or in some other way, the workman stands inside of it facing the end where the binders are attached, he takes a small handful of straw and lays it with the butt ends projecting about 3 inches beyond one of the outer pieces of warp, and secures it by passing the second binder over it and tying this by means of a half hitch to the warp. Another handful is similarly placed on the opposite side, the small or grain ends of the straw will then overlap one another in the middle of the mat; all the binders may then be fastened.

Layer after layer of straw is put on in this way, the operator working backwards, until the mat is of the desired length. The binders may be lengthened as required, by knotting other strings to them. Care is required to maintain a uniform thickness by putting on the straw in equal quantities, and compressing each layer to the same degree by the binders. When finished, the mat is to be cut from the frame, and the ends securely fastened. The sides are trimmed with a sharp knife, using a straight edged board as a ruler. Mats of this kind, if properly cared for, will last several years. They should, of course, be thoroughly dried before storing away. The engraving given above shows how the successive portions of straw are bound to the warp.

Public Parks.

As some of our readers doubtless have occasion, in their several localities, to superintend the planting and arrangement of public grounds, we venture to suggest a few ideas on the subject.

Large public grounds should be provided with roads for carriage-drives and for horseback riding. These should be wide enough to admit of turning round and turning out easily, and they should be hard and smooth. There should be one main drive, laid out near the boundaries, though not running continuously on the same line, nor in sight of the fences. From this main drive, cross-roads may occasionally diverge, to allow of shorter and more varied rides to such as may wish them. But these subordinate roads should be narrower, and they should be made as inconspicuous as possible. Walks may also be laid out by the side of the main road, for the use of pedestrians. A more desirable place for walks, however, will be found in the interior portions of the ground, away from the dust and exposure of the traveled road. These should be arranged so as to command as great a variety of scenery as possible; now ascending eminences

to get views of distant hills, or spreading country, or sheet of water; then descending into quiet valleys, rolling over grassy lawns, skating ponds or streams, or winding among rocky dells. Whoever wishes to examine some of the finest examples of road and walk making, should visit the Central Park in this city, especially the "Ramble," and he will learn more in a few hours than we can teach him in many pages.

The planting of such a park will require less study than a smaller piece of landscape-gardening. A leading object will be to secure shade. Of course, then, the borders of the drives and paths should be fringed with trees. Yet they should not be set in continuous lines and close together, thus excluding free views of the grounds. In addition to this, wherever fine prospects can be had of distant scenery, the outlook should be left open and unobstructed. Here and there, also, groups and masses should be planted, running out into the park, to break up the monotony of the single line.

If the space is large enough, groups and scattered trees may be planted at intervals; but they should be set sparingly, as too many serve to contract the ground and shut out pleasing views. Nothing, however, can be finer than a few choice single trees, set in the open lawn, with ample room to develop and exhibit their perfect forms. Wherever the land is rocky and hilly, spiry-topped trees are specially appropriate; on fat, rich plains, those of broad, rounded heads; by water-courses, willows and other pendulous trees are most desirable.

The boundary fences should be concealed by hedges and low trees. Mr. Loudon laid it down as a general rule that, "whatever the height of a tree or shrub may be, provided it be greater than that of the human eye from the ground, it ought to be placed at such a distance from the walk or road, as that the eye may see the top of it at an angle of from 30° to 40°. A tree that grows forty feet high, ought to be placed about fifty feet from the walk." Here he is speaking of trees set in parks for observation rather than for mere shade. Another excellent rule was this: "Every tree or shrub, however low, ought to be placed at such a distance from the walk, that its branches, when fully grown, shall not reach nearer to it than from one to two feet." A rule that ought to be printed in letters of gold, and hung daily before every tree planter!

We need hardly add that the soil in which the trees are to be set, should be properly enriched, subsoiled, and drained. They will then make a vigorous growth from the outset. That the ground around the trees should be worked over annually with hoe and spade, and kept free from weeds for several years, is another obvious fact. For the first year or two, the roots should be mulched with coarse litter.

A park is not complete without convenient seats. These should be made of the plainest materials, solid and not likely to get out of repair. The appropriate places for them are, both under the shade for Summer use, and in the sunshine for Spring and Fall; in quiet, retired nooks, and on high points commanding views of surrounding scenery. Set anywhere and everywhere, they will hardly come amiss.

THE NORWAY MAPLE differs considerably from the common rock-maple. Its bark is smoother; the buds in Winter are larger and blunter; the leaves are larger, darker, and there are more of them. They are not white on the under side. The flowers in Spring are yellowish. The tree is a rapid grower, and easily

adapts itself to all soils. In Europe, the wood is highly valued for cabinet work; it resembles, somewhat, our birds' eye maple. Plant it.

Seedling Fruit Trees.

It is singular that the majority of our most valued fruits are chance seedlings, originating without the intervention or care of the cultivator. This is especially true with pears and apples, which are so long in coming into bearing that few have the patience to make the trial. Peaches, apricots, and other stone fruits, which fruit comparatively early from the seed, are often multiplied in this way. The raising of seedling pears has received a new interest from the labors of M. Gregoire Nelis, in France, and of the veteran pomologist Thomas Rivers, in England. The former has devoted 32 years to his experiments in raising pears from the seed, and has in that time raised 150 varieties worth perpetuating, and of course, at the same time, thousands which were rejected as unfit for introduction. M. Gregoire Nelis' method of hastening the fruiting of the seed, is to transplant annually; this gives them a compact growth and promotes the formation of fruit buds. In this way, fruit is obtained in 6 or 8 years from the seed. The experience of Thomas Rivers is given in the Gardeners' Chronicle, in an article which is so interesting that it is a matter of regret that its length prevents us from re-printing it. He cultivates the pear seedlings, in pots in the orchard-house, keeping them in 10 inch pots, and root-pruning and re-potting every season. Treated in this way, the trees may be expected to come in bearing in six years. A general tendency is found in seedlings from late pears, to mature much earlier than the parent. His results with the progeny of well known varieties, is full of interest to the pomologist, but would not be so to the mass of our readers. Peaches and nectarines grown in pots will produce fruit in three years from the seeds, and those raised from late kinds show, like the pears, a tendency to produce early varieties. In the course of Mr. Rivers' experiments he found that nectarines were produced from peach stones, and that the stone of the nectarine would sometimes produce a peach tree, thus confirming the fact, which has been doubted by some, that the two fruits are only varieties of the same species.

The improvement of our various fruits by seedlings from good sorts may well claim the attention of those who have time and means to devote to it, yet there are still "native fruits" in many localities which should be brought into notice. Several of these have been presented at the Fruit Grower's meetings held each Thursday at the office of the *Agriculturist*, and we invite those who have seedling fruits, possessing desirable qualities, to bring or send them to these meetings for examination of their merits.

Trees for Nurses.

A good deal is said in books and papers in favor of setting out a surplus number of trees in a plantation, (afterwards to be removed) for the sake of sheltering those which are to remain permanently. They are planted, also, partly for the sake of giving immediate effect.

But experience is beginning to testify against the practice. It is found that when the ground is so thickly filled up with trees, the soil becomes quickly exhausted, and the permanent trees make only a slow growth. Moreover the nurses overgrow and shade the permanent trees so

as to injure their shape. The lower branches make a much feebler growth than they would if exposed to abundance of light and air, and the higher branches run up in a spindling manner. Evergreens especially suffer when crowded by nurses. Their base branches, which it is so important to preserve, soon die out. And yet, if caution be used, such trees may be sometimes employed. For instance, they may be set on the most windy and exposed side or sides of a favorite tree, if they are planted at a considerable distance, and if they are removed after the first or second year. The danger is that they will be left standing several years, until they have injured the tree beyond recovery.

Managing Trees in Windy Places.

Various plans have been tried to keep newly set trees erect in bleak places, and to preserve their branches from being blown and whipped out of shape. Stakes of several kinds are used. Some are set close to the trunk and bound to it by wisps of straw or bands of leather; but these are soon displaced, or the tree gets badly chafed. Then, a stake is often set a foot or more from the tree, and the two are fastened together by cords of some kind; yet here, too, the cords may be broken before the planter is aware of it.

We have tried a plan lately, which has some merits. It dispenses with stakes altogether. After the tree is planted, four or five stout pegs are driven into the ground, in a circle around the tree, and about under the ends of the branches. Flat leather bands, or stout pieces of listing are tied to the branches on opposite sides of the tree. Strong cords are then drawn from these to the pegs and tied. This keeps the tree from swaying in any direction. On the most windy side, double the number of cords are used, to preserve the branches in good shape. To this we have added, for weeping trees, light weights suspended from limbs which, on account of the wind, did not take the pendulous habit that was desirable. *

For the American Agriculturist.

Northern Spy Apple.

I think "Pomologist" has extolled this apple too highly on page 367, December *Agriculturist*. My experience with it is not favorable. In the Spring of 1850 I set out four young trees of this variety, and grafted the tops of three old trees with cions cut from the young trees. None of the trees showed even a bloom until 1860. They bore well the two following years, but there were not two barrels of marketable fruit from the seven trees. The soil on which the trees stand, is a sandy or gravelly loam, which produced over fifty bushels of corn per acre. I do not find the Spy keeps any better than Esopus Spitzenberg, and not as well as R. I. Greening, Baldwin, Roxbury Russet, etc. The flavor is good, and the fruit retains its freshness for a long time, which is about the only thing I can find in its favor.

In the Spring of 1855 I grafted an old tree with Baldwins, and had two barrels of fruit from it the third year, seven barrels the fifth year, and six the seventh year, making fifteen barrels of saleable apples in seven years from grafting.

A. G. PERCY.

Wayne Co., N. Y.

REMARKS.—The Northern Spy is one of our most variable apples, though nearly always of good flavor. It is not suited to a wide locality, but in many places, on rich soil, it does remark-

ably well. It is certainly late in coming into bearing, and it does not show all its good qualities at the first fruiting. It continues to improve with age. In some localities, however, and on poor soil, it often proves quite refractory, and on this account it has not received the universal commendation, which an apple of such fine appearance, and agreeable, sprightly favor would appear to deserve.

Experience with Peach Trees.

To the Editor of the American Agriculturist.

Ten years ago I bought and transplanted two hundred peach trees, which netted me two years ago, \$200. The soil was too rich, and they are now nearly all dead. Four years ago, I bought an orchard of 900 peach trees, and 300 apple trees set between them. These trees are now 10 years transplanted, and last September they netted me \$500. They were set on thinner soil than the first lot, except in one corner where they have all died. I am satisfied that peaches require the same kind of soil that potatoes do, to prevent their rotting—thin, or poor upland. Cultivation is necessary to fruit-bearing. If the orchard be seeded, you need not expect many peaches. The kinds I like best, are: old Mixon, Crawford's Early, Crawford's Late, Melocoton, Smock, and Morris White.

The peach borer is an inveterate enemy, but the "yellows" is the great destroyer. Perhaps this disease is superinduced by rich soil and common farm yard manure. I think mineral manures only are necessary, and little of them if the land is properly cultivated by raising potatoes, or other low crops—or without crops.

Fairfield Co., Conn.

G. W. B.

Fruit Growers Meetings.

Excepting during the holidays, these meetings have been kept up regularly, and are increasingly interesting. They are held at 1 o'clock P. M. each Thursday, and all interested in fruits and kindred subjects, are invited to attend. A standing committee consisting of Chas. Downing, S. B. Parsons, W. S. Carpenter, A. S. Fuller, and Dr. I. P. Trimble, has been appointed for naming new fruits, identifying old sorts, and investigating whatever is about being sent out with high sounding names and large claims upon the credulity of the community. This will guard against imposition and fraud. After the adoption of a list of 20 varieties of pears recommended for planting, as published on page 17, January *Agriculturist*, a committee was appointed to bring forward lists of the 6 best grapes for outdoor cultivation. Several discussions have been had over the grape question, and sundry lists have been presented, but no selection has yet been adopted: the decision will soon be made and published in ample season for Spring planting. A similar committee to bring forward apple lists has also been appointed, and will agree upon a report in a week or two. The list will probably be adopted in season for publication in our next number.

A great many winter pears have been sent in from time to time, among which the Vicar of Winkfield is most abundant. When well grown and ripened with care, they are really good; some members expect to have them until February 1st. The Lawrence, however, is pronounced to be among Winter pears what the Seckel is among the Autumn varieties. It was advised to plant it on the pear stock. The

specimens of the Glout Morceau, frequently brought before the meeting, proved very fine. Though this variety is proverbially slow in coming into bearing, one member reported a barrel of fruit picked from a standard tree planted nine years ago.

W. S. Carpenter questioned whether the so-called dwarf trees retain any of the quince roots after being planted a few years. Nurserymen universally advised to plant dwarfs a little below the junction of the pear with the quince, so that the pear might put out roots of its own. These roots soon become the leading ones, and and from disuse and deep planting the quince roots soon decay. Out of a large number of dwarfs planted some years ago, and recently moved, only one tree retained any quince roots.

Prevention of Sap Blight.

John Grable, Doniphan Co., Kansas, writes to the *American Agriculturist* on this subject as follows: "Heart and Bigarreau cherries, that have been planted in north-western Missouri for 15 years past, have come to nothing, while Morellos do well. This is owing to their being killed by sap blight, which I have noticed to occur in February. It is caused by sudden thaws, followed by hard freezing, which loosens the bark on the tree, except a little on the north side. A tree under these circumstances will survive for a while, but when the blight extends around the trunk, it is 'done for.' This happens, on an average, every four or five years. As far as my experience goes, the best remedy is, to prune the trees to low heads, and wrap the trunks with strips of old drab-colored cloth, which preserves them from sap blight, and from rabbits. Two years ago, I planted 23 apple trees in October, and thirteen of them were ruined by sap-blight in February. This seemed to prove to me, that Fall planting was more critical than Spring planting, as there were many trees of about the same size, planted in the same locality in the Spring previous, and not one of them suffered from the blight."

Rotation in the Garden.

Probably many readers of the *Agriculturist* are puzzled when they see a plant spoken of as belonging to a certain family. By this is meant that different plants, though unlike in many particulars, have some points in common, and have, as it were, a family relationship. Those who make an especial study of plants, group all that are known, into a not very large number of families; their reasons for doing so are sometimes drawn from something in the flower or fruit which persons in general would not notice, and again upon resemblances which are sufficiently striking to be observed by every one. Thus, the bean and the pea are so nearly alike in flower and fruit that we naturally suppose them to be related, while carrots and celery do not seem to go together so readily, because we are not accustomed to see the flower and fruit. Plants of the same family, being made on the same general plan, are commonly very much alike in their properties, and take up very nearly the same substances from the soil. In the rotation of crops it is desirable that the soil should be occupied not only by a different plant, but by one of another family from that which it previously bore. In farm cropping, the number of kinds are so few, that there is no difficulty in fulfilling this condition; but

in the garden, where a number of sorts are grown, the arrangement of a proper rotation requires some forethought. The following grouping of the common garden vegetables will assist in making out a proper system of succession. Turnips, cabbages, cauliflowers, borecole, broccoli and radishes belong to one family—parsnips, carrots, parsley and celery, to another—and so with lettuce, endive, salsify and scorzonera—beets and spinach—cucumbers, watermelons, and muskmelons—potatoes, egg-plant and tomatoes—beans and peas—onions, leeks and shallots. Onions are an exception to the rule of relations, and are successfully grown year after year upon the same soil. Root crops, which grow mainly in the soil, should be followed by some crop cultivated for its leaves, etc. To illustrate—in the above enumeration, it will be seen that carrots should not follow or be succeeded by parsnips, parsley or celery, as they belong to the same family, nor by beets and other root crops—but may precede or follow anything else. Where circumstances render it necessary to plant a crop successively upon the same ground, the soil should be well manured and deeply and thoroughly worked.

Garden Walks for Exercise.

A friend writes us that, in his large grounds, he has laid out a series of walks so arranged that by going over one track a certain number of times, the extent is a mile. Against a wall he has affixed an iron strap pierced with holes, by the side of which is a pin suspended by a small chain, so that the pedestrian, by moving the pin from one hole to another every time he passes it, knows exactly the extent of his walk.

This is all very well, when one can't do better. We have known persons exercising by the clock in their rooms, or pacing back and forth over a few rods of pavement, and amid the same scenes, by the hour. But it strikes us that when one wishes a smart walk, he had better launch forth from his garden, and perambulate the public street, so that he may see new faces and new scenes. Or, if there is work to be done, put on the garden outfit, and with hoe and water-pot or other implement, he will soon get pleasant healthful exercise. This is the writer's experience.

Grape Vines.

When the demand for choice grape vines is greater than can be supplied by the ordinary modes of propagation, some nurserymen multiply them by cuttings of the green wood. It is the experience of many of the best cultivators that vines propagated year after year in this way deteriorate and become less hardy. The Delaware is cited as having especially suffered from this mode of treatment. It seems very likely that continued propagation from unripe shoots would produce weak plants. We should not think of sowing from seed so immature that it is just capable of germinating; a feeble plant would be produced—and, though the circumstances are not precisely the same with cuttings, there is no doubt that strong well-ripened wood will give plants of greater vigor than can be raised from green cuttings.

LILIES FOR CITY GARDENS.—These showy flowers are worthy an occasional place in even small collections of plants; but all are not well adapted to growth in the smoky city atmos-

phere. The large white, and the speckled orange do well; the latter will thrive under trees. The Martagon, Thunberg's, the tiger-streaked, and Cateby's, require the freer air of the country.

Miniature Rustic Plant Stand.

While recently at the Horticultural warehouse of our friend, C. B. Miller, who is well known in this vicinity, as the Secretary of the Brooklyn Horticultural Society, we observed the beautiful miniature rustic plant stand, represented above, devised by him we believe, and its appearance was so pleasing that we ordered an engraving of it to be made. It consists of a simple oval shaped box, with slips of wood tacked around the sides, the bark still adhering, and an arched frame of vine-work raised above it, the whole being nicely varnished. A shell containing a trailing plant rests upon the top; underneath this is suspended a miniature globe filled with water in which swims a small gold fish. Ferns and other plants are grown in soil covered with moss in the box at the base, and delicate vines are trained to the side frames. The whole forms a unique and tasteful ornament for the sitting room, costing but little to make or to purchase.

City Gardens.

Gardens in towns, especially when of considerable age, are apt to become sodden, sticky and infertile. The trees and plants set out in them do not grow well, but become mossy, cankered, and even die outright from no apparent cause. It is not generally from want of manure, but oftener from too much of it; not from want of water, but oftener from an excess of it; not because the soil is too new, but because it is too old.

But to be more particular: whoever has such a sickly garden, should look first after the drainage. Very likely, he will find the pipes choked up, and consequently the pores of the soil flooded and clogged with matters which ought to pass off through the sewers. Water and ma-

nure are good enough in suitable quantities, but too much are hurtful; just as food and drink are good for the animal frame when moderately used, but in excess are injurious. Standing water fills up the interstices of the soil, preventing the needful free circulation of air to the roots.

The drainage having been overhauled and cleaned, take the soil itself. Most likely, it will need trenching, and bringing up some of the subsoil to mix with the worn out top-soil. Or, cart off some of the surface earth, and bring in an equal quantity of maiden loam from the meadows of the suburbs. By some means or other, change and freshen the soil. An occasional syringing of the foliage of trees and plants will be useful, to clean off the dust and smoky deposits of the city, but it is most important to put the soil in proper condition, and keep it so.

Walls for Gardens.

The custom of surrounding gardens with substantial walls, prevails in England and Scotland, more than in our own country. The principal reason is, that there the light and heat of the sun are not intense enough to ripen some of the choicer fruits in the open ground; these need to be concentrated by some artificial means. With us, if peaches, pears, plums, and grapes, are trained close upon the sunny side of a wall, they are very apt to be dried up and injured, both in foliage and fruit. Yet, there are uses to which walls and high fences may well be applied. In all elevated and bleak places, they are serviceable in breaking the force of winds, and preventing the too rapid radiation of heat from the soil. For this purpose, they are specially useful in the early Spring. In a garden so protected, grape-vines, cucumbers, melons, etc., may be brought forward much earlier than in one exposed to cold breezes on all sides.

Such walls are very useful in protecting grape vines against unseasonable frosts. We now recall a locality near the center of this State, where it is almost impossible to raise grapes, on account of the untimely frosts in Spring and Fall. Sometimes the late spring frosts destroy the fruits in the flower, or the September frosts freeze them before they are ripe. Not to be outdone by King Jack, a few enterprising fruit-growers have built walls, mostly of brick, on the north side of their gardens, on which they raise grapes with considerable success. The accumulated heat of the day radiates slowly during the night, and preserves the vines from harm, even when other tender things in the open ground of the garden are cut off. These walls are also furnished with a coping, about a foot wide, sustained by brackets like the cornice of a house. This coping is removed during the mid-summer, to allow the foliage the full benefit of rain and dew. To prevent the vines from being scorched by the sun, they are trained upon a trellis which is set off several inches from the wall; this allows the free circulation of air behind. Upon a wall, facing in almost any other direction than due south, there would be little danger from sun scald.

The California Pitcher Plant.

The locality for that rare California plant, the *Darlingtonia Californica* has been visited by Prof. Brewer of the Cal. State Geological Survey. It grows in a small swamp near Mt. Shasta, at an altitude of 2,500 feet. The leaves are somewhat like those of our common pitcher plant

(*Sarracenia*), are about two feet long, and have the opening of the pitcher partly covered by a curious two-lobed appendage, shaped somewhat like the tail of a fish. Though the plant was first discovered by the botanists of the U. S. Exploring Expedition some fifteen years ago, it has never yet found its way into cultivation. The lovers of plants will be glad to learn that seeds have been placed in skillful hands, and that there is a hope that our collections may be enriched by a plant which is not only curious, but which bears a name dear to every American botanist—that of the venerable Doct. Darlington of Penn.

An Area Conservatory.

Those who have a real taste for Horticulture, will find a way to gratify it, no matter how limited their means or circumscribed their space. Hood's Mrs. Gardiner, who proposed to "cucumber" in her wash-boiler, is only a slightly exaggerated illustration of the way in which a passion for plants will stimulate the inventive faculties. A correspondent has sent us a drawing and description (for a long time crowded out) of an extemporized conservatory, which is here presented with the belief that many of our readers who live in cities will be glad to adopt the plan, or such modification of it as their premises may require. The engraving represents the area at the back of the house, enclosed by sash, thus affording a conservatory 20 feet long by 8½ feet wide, to which the balcony serves as the roof. One or more of the sashes are made movable, to allow of ventilation and ingress. By leaving the kitchen windows open, the temperature is ordinarily sufficiently high; but to ensure this in severe weather, hot air is brought from a furnace in the cellar by means of a flue. Where there is a water back to the kitchen range, the heating might be accomplished by pipes connected with it. The moisture from the operations of cooking and washing, generally keeps the air in the conservatory sufficiently humid, but when it is necessary to introduce hot air from the furnace, care is taken

that it shall pass over water in order to avoid a dry heat. The whole cost of the structure was not over \$30. No doubt many of the readers of the *Agriculturist* have felt the want of a place for their plants, and will be induced, upon seeing this simple plan, to examine their premises with a view to a similar contrivance. Such a structure admits of a large number of pots, and adds much to the attractiveness of home.

A HINT IN TRANSPLANTING.—The practice of lifting a tree up and down and shaking it, at the time of transplanting, is of doubtful utility. The aim is to settle the dirt closely around the roots; but then it draws the roots out of their proper

place, and bends and breaks many of them. Such trees often show that they are injured, by throwing up suckers. A better way is to work the soil in among the roots with the hands, and perhaps apply a little water to wash it in, when the work is about half done.

THE HOUSEHOLD.

Good Feet Warmers.

The best feet warmers are: frequent applications of water and a coarse towel, dry woolen socks, thick boots, and exercise. These will usually keep the feet of an active person comfortable in any but the most excessively cold weather. Sometimes, however, it is necessary to take a long ride when the thermometer marks a temperature near zero, during which brisk circulation of the blood can not be kept up by exercise, and without some additional precaution, the feet are liable to great discomfort. If the socks be dry and the feet be well warmed before setting out, the heat may be retained for a long time by wearing heavy woolen socks or moccasins over the shoes. These can be made of extra stout yarn, or more cheaply and easily by sewing together properly shaped pieces of thick blanket. Moccasins of buffalo skin, with the hair inward, are admirable protectors of the feet in traveling. Occasionally, owing to feeble health, the circulation of blood is too sluggish to generate a comfortable degree of heat in the system, and persons suffer from cold, whatever the amount of clothing worn. The extremities, particularly, feel the want of a full supply of natural animal heat. In such cases heat must be derived from external sources. Vessels of hot water, heated blocks of hard wood, bricks, etc., are commonly used to keep the feet warm. A better article for this purpose than either of the above named, is a block of soap-stone, which retains heat for a very long time. Enclosing it in a convenient woolen bag will keep it warm considerably longer than if it be left exposed. A correspondent of the *Agriculturist*, (E. S. Osborn, Suffolk Co., N. Y.,) who has tried this material for several years, has found it so good that she thinks it would be an excellent charity to furnish such blocks in large numbers to the poor in cities. Perhaps it might abate some suffering, provided enough fuel to heat the blocks with, were supplied at the same time.

Slipping Down—"Creepers."

The number of bruises, broken limbs, sprained joints and other casualties resulting from slipping down on ice-covered ground, if carefully summed up, would amount to hundreds of thousands every year. Suppose that among the twenty-five million inhabitants of the colder States and British Provinces, only one person in a hundred should fall down so as to receive injury. This would amount to **250,000**—quite an army even in latter days. Old persons who are not agile, and whose bones are brittle, and least likely to unite quickly if broken,

Fig. 1.

Fig. 2.

are most apt to suffer. We have known of several such cases of very serious injury. There are several contrivances to prevent slipping, two of the simplest of which are represented in the accompanying engravings, that are somewhat old, but not generally in use. Fig. 1, is a piece of flat iron, split twice at each corner with the sharp points turned down, and the middle pieces turned up and punched with holes for straps. Fig. 2, shows the method of attaching it to the boot or shoe just forward of the heel. Any blacksmith can readily make them,

or they may even be made at home. The length of the points is to be proportioned to the height of the heel; the points will need to project scarcely more than $\frac{1}{2}$ inch below the heel. The housewife will of course see that these heel pieces or "creepers" are left behind at the door.

Fig. 3, represents a form usually sold at the hardware stores for about 25 cents per pair. They are of cast iron, and are fastened on, or loosened, by turning the screw (A) at the heel. The points (B) are turned inward so as to catch into the leather, and hold them on firmly.

Fig. 3.

Potatoes in the Bins.

INTERESTING FACTS FOR "SPROUTERS" TO THINK OF.

If the family supply of potatoes has been stored in a moderately warm place, they will soon need attention. They must be looked over and the sprouts rubbed off—or 'sprouted' as it is termed. A dark, cool and dry place is best. The cooler they are kept without freezing, the less likely they will be to start. Rubbing off the sprouts is good indoor work for stormy weather, but as it is rather dirty and monotonous, it is not a job that is much relished. Persons do not generally like any work, however easy, provided it is merely mechanical, and offers no employment for *mind* as well as the hands. Let us see if there is not something interesting in sprouting potatoes. Many of the potatoes will be found to have a bit of stem attached—the remains of an under-ground stem, of which the potato is the enlarged end. It is the channel through which the potato received all its nourishment, and grew to such rotund proportions, but like many who have grown fat and prosperous, it seems to have forgotten the means by which it became so, and instead of giving back any of the rich stores it has received through it, the over-fed potato leaves the little stem to perish. The new sprouts all start from the eyes of the potato, which are much more numerous and closer together as we go from the stem end. These potato eyes are arranged in a peculiar manner. If we start with an eye near the stem end it will be found that the eye next above it is placed a little to the right, the next a little to the right of that, and so on, thus forming a regular spiral. The arrangement is best seen in the longer varieties. The sprouts start first from the end farthest from the stem, and if these are allowed to grow, many of the others will not start at all. The potato having once made up its mind to grow, is not to be easily thwarted, and if all the sprouts are rubbed off, the operation very often has to be repeated a second or third time.

If we examine a potato eye closely, several little spots will be observed; each of these are buds from which sprouts may spring. If one or more of these starts and are allowed to grow, the rest finally perish; but if the first sprouts are removed then the reserved forces are called up, and a new crop of sprouts appear; and this is repeated again and again until the last one of the supply of super-numerary buds is entirely exhausted.

The potato looks like a stupid thing, but it seems to show a kind of instinct. The sprouts in the bin or barrel, far away from the earth, throw out roots which go traveling off in search of sustenance—as if knowing that the supply for the young plant, contained in the potato, could not last long.

Inside of the potato curious chemical changes are going on. The starch which is put there to supply food for sprouts or young plants, undergoes a transformation. It has to be moved in order to aid the young growth, and as it is not soluble in cold water, it is changed so that it can pass to where it is needed. It is partly converted into sugar, as may be seen from the sweet taste poorly kept potatoes have in the spring. We have not said all that the occupation of sprouting potatoes suggests—but enough we trust to show the readers of the *American Agriculturist* that there is much to learn about common and every day things, which apparently possess little of interest.

To Prevent "Chapped Hands."

The writer was formerly much troubled with chapped and cracked hands, so much so as to constantly feel uncomfortable. Latterly, I have been entirely free from this source of trouble, and, except when obliged to handle frozen substances, I no more think of wearing gloves or mittens on my hands, than I do of covering my face. This good result I attribute wholly to a hint given in my *American Agriculturist* a few years ago, which I would like to have repeated for the benefit of others. It was in effect as follows: The cuticle or scarf skin is designed as a handprotective covering, and when sound, it serves this purpose admirably. Pure water does not affect the cuticle; but add a little soap or other alkali to the water, and it at once attacks the cuticle and will in a short time dissolve it off. I now avoid the use of soap as much as possible, using a brush to remove most kinds of soiling. When soap is absolutely required to remove oily or greasy matters, I keep it on the hands as little time as may be, and rinse off the last vestige thoroughly, leaving none to corrode and crack the outer skin. Generally, I dip the hands in water in which a few drops of vinegar have been poured; this neutralizes the alkali of the soap. Wife does the same on washing day when the hands must be put into soap suds. I formerly applied vinegar to the face after shaving, but now use a little cheap Cologne water, or common whiskey, which removes the alkali, and keeps the whiskers black—not faded as when nothing was used after the lather. FARMER.

A Short Chapter on Bonnets.

The Fashion in 1860.

The present Style.

What Next?

About Illuminating or Coal Oils.

Perhaps no household topic is of more general interest than that of the oils, to which we are so much indebted for the comfort and cheerfulness of our homes. A few years has brought a great revolution in our domestic economy, which is nowhere more strikingly seen than in our methods of illumination. Whale oil gave way to the dangerous camphene and burning fluid, and these were in turn superseded by coal and mineral oils. The whales are left comparatively unmolested, it being much easier to catch a few tons of coal than it is to capture one of those monsters. Turpentine, from which camphene and burning fluid are manufactured, is so scarce, that were these articles in general use, the demand could not be supplied. Happily the facility with which better illuminating oils can be procured from coal, and the wonderful discovery of the oil wells, have given us a better and cheaper light. Our readers are well aware that there are two kinds of mineral coal; the hard or anthracite, and the soft or bituminous. The latter, which is the kind most known at the West, burns with a flame, and is the kind used in making the oils and the gas for lighting cities. If bituminous coal be heated in a closed iron vessel, shaped like a bottle, the portion which would have burned with a flame, had the coal been on the open fire, will be driven off as a gas, and may be lighted at the mouth of the bottle. In gas making, the coal is thus heated, and the gas, after being properly purified, is carried by pipes a long way

even miles from the place where it is made, to be burned. The success in gas making depends upon using the proper amount of heat to convert into gas as much as possible of the volatile matter of the coal. A lower degree of heat slowly applied, produces from the coal but very little gas, but what would have otherwise been gas, is obtained as a thick tarry oil. This is the first step in preparing the coal oils, and by refining this crude oil, several products are obtained. Sulphuric acid (oil of vitriol) is added to the crude oil which helps separate the tar and other impurities, then lime is added to neutralize the acid, and the thinner portions of the liquid are poured off and distilled. This liquid contains several distinct oils which have different boiling points. In the distilling processes the heat is applied very gradually; at about 80°, a very volatile liquid is obtained and as the heat is increased, other oils having higher boiling points are distilled, the last of these requiring a heat of over 500° to convert them into vapor.

The liquids first obtained, which boil at so low a degree, are unsafe to use for illumination. They are known as Naphtha and Benzine, and are of great value in the arts. They have the power of dissolving all greasy and resinous substances, and are used for cleaning clothing, dissolving india rubber, mixing with paint in place of turpentine, etc. After these very volatile oils have distilled, others are obtained, having higher boiling points, and these are used as burning oils, and are known as Kerosene, and by a number of other trade names—all being essentially the same thing, but differing in their color, density and boiling points. The oils which are obtained by distilling at a high temperature are used for greasing machinery. There is deposited from the oils after distillation, a whitish substance which is collected, purified, melted, and made into cakes. This is Paraffine; it looks something like white wax, and is made into beautiful candles of great illuminating power. It melts so readily that it cannot be used pure for candles, hence those sold as Paraffine candles are in part composed of spermacetti and other substances, to render them firm in warm weather. Great quantities of illuminating oil are obtained from the Petroleum or oil from the oil wells. Here the first step in the process is done by nature, and crude oil is furnished ready for the refining process. The illuminating oils from Petroleum, known as Carbon Oil, and by other names, are essentially the same as those made from coal. All these consist of mixtures of oils, having different boiling points, and those are the safest which have the least admixture of naphtha. Kerosene and similar oils, when properly prepared and burned in suitable lamps, are not liable to form explosive vapors, but if from carelessness or fraud on the part of the manufacturer, they contain much naphtha, they are dangerous. No oil is safe to use which will give off an explosive vapor below 110°. The coal oils in the market generally form an explosive vapor when heated to 130° or 140°, and those from petroleum do so at 100° to 120°. The density or weight of a sample of oil is no indication of its freedom from explosive qualities; this can only be ascertained by experiment. Apparatus is made and sold for the purpose; but a sufficiently correct test can be made by putting a little of the oil in a tin cup, which is to be placed in a large vessel containing water. A thermometer is placed in the water, and the whole put upon the stove, and allowed to heat very slowly. A lighted match is applied from time to time to ascertain when the oil in the cup forms an explosive vapor, the temperature at which this takes place is indicated by the thermometer. The light should not be applied to the oil, but should be held just within the edge of the cup. It is wonderful to think as we sit by the cheerful coal fire and read by the light of a Kerosene lamp, that we are enjoying the same light and heat which came to the earth ages and ages ago. The plants which produced the coal and rock-oil grew by the aid of the sun's rays, and—as every plant is now doing—looked up a portion of light and heat in their stems and leaves. Whether we burn the wood which has grown within our own observa-

tion, or that which grew longer ago than we can calculate, and has become coal, we only set free the light and heat which the sun furnished it to enable it to grow. Then how wonderful the human skill which takes these "black diamonds" from the dark mine, and by aid of chemistry makes them to shine and fill our homes with their brilliancy.

Tim Bunker on Extravagance.

"Forty-five thousand dollars for jewelry in New-York, at one store, in one morning!" said Mrs. Bunker as she took off her specs, and laid down the Times, in which she had just read that account.

"And how many stores do you 'spose they've got in New-York, where they sell them 'ere fixins," inquired Mrs. Seth Twiggs, who had dropped in with her knitting, and sat in a meditative mood, while Mrs. Bunker read the war news. (Seth used to take the daily paper himself, but since the rise in price, he says he can't afford it. Twelve dollars a year for a daily paper, he says, is a leetle too mighty for a poor man who works for his living. That would more than buy a barrel of flour, and it only takes two barrels to carry his little family through the year. I have noticed, however, that he and his wife are more neighborly than common, since they stopped the daily paper. I am not particularly sorry, for Seth is good company, if it wasn't for his everlasting pipe, which I abominate, as all sensible people should. What upon earth a man should want to make a chimney of his nose for, I never could see. We are kind o' lonesome, since Sally got married, and John went off to the war, and neighbors don't come amiss. Seth also has a son in the war, and we have a considerable fellow feeling.)

"There's a hundred of them stores at least," replied Mrs. Bunker.

"You don't mean a *hundred* on 'em!" exclaimed Mrs. Jacob Frink, whom the neighbors all call "Polly," for short—except a few of us older people, who say "Annt Polly."

"What a sight of silver spoons and forks, teapots and tureens, fruit knives and porringers, they must have down there, if all the stores sold as much as that 'ere one you read about."

"It would make four millions and a half of dollars, spent in gewgaws in one morning," said I, willing to increase Annt Polly's astonishment.

"You don't say so, Squire Bunker!" said she. "That is more than Jacob could carry in his cart."

"Well I guess it is. It would line Broadway with silver, from the Battery to Central Park," said I.

"Provided you didn't lay it on too thick," added Mrs. Bunker, squirming in her chair, at the extravagant expression.

"I said *line* it, Sally, not *cover* it." I responded.

"Wa'll, it is an awful sight of money any way!" said Annt Polly. "I fear I should covet, if I see it."

"And where do you suppose it all comes *from*?" asked Mrs. Twiggs.

"I can tell you where some of it comes *to*," answered Annt Polly. "You see Kier has just got home from the war, wounded in his left arm. And he stopped in New-York jest to see the sights, and to get something to bring home to the old folks, and to his family up at the White Oaks. And don't you think he brought me home a pair of gold specs and a gold thimble for his wife, and a silver trumpet for his boy, Jacob Frink jr., who aint more than six months old. Now we didn't need these things any more than a cat needs tew tails. I had a pair of steel-bows that Jacob got me five years ago, and they are jest as good as new, and I can see in 'em jest as well as in the new ones, and a trifle better. And then his wife had thimbles enough, rather more than she used, any way, judging by the looks of Kier, when he used to drive the coal cart. She never kept him tidy, and I don't believe gold thimbles will help her ease, if she had a earload of 'em. And then as to that boy, he won't be big enough under a year to blow a squash leaf squawker, to say nothing of trumpets. A silver trumpet! It is the only article of silver in the whole neighborhood of the White Oaks, barring the small change they've got stowed away in their stockings, agin it comes

into fashion agin. Now, Kier paid ten dollars for that 'ere trumpet, and he had no more use for it than his wife has for a pianny. You see, he had just got paid off, and he had never seen so much money before in one pile, in all his life. He wanted to make a sensashun in the White Oaks, and I guess he did it, when he bought that article. Not less than twenty five dollars, the price of blood as it were, all spent for nothin. I was riled when I see him unpack the things. Ah, if he had only got a raw hide for that youngster there would have been some sense in it."

Aunt Polly paused for breath, and looked red in the face as she doubtless remembered the walloppings she had bestowed upon Kier in his juvenile days. But there is a deal of sense in what the old lady says. You see this war has made money awful plenty, such as it is, among a certain class of people. It has got into new hands, and they are itching to let the world know that they have got it. I know of some fellows that have gone to the war that are earning more money for their families than they ever did before. There are Tucker's two boys that never did any thing but hunt, fish, and loaf, but they are now earning their rations and thirteen dollars extra, a thing they never did before, without the extra. There are hosts of contractors for steamboats, for iron-clads, for army clothing, for horses, for mules, for forage, for flour, for rations of all kinds, that are getting a big slice, and piling up money by the hat full. This money is distributed all through the country, and farmers come in for their share. Well now, it is mighty natural when folks that have been stinted for a good while, when they get hold of the cash, to make it fly. So it goes for jewelry, for bonnets, and silver trumpets, and all sorts of jimeracks that tickle the women and children, and don't do any body much good.

You see, George Washington Tucker jr., that enlisted in the beginning of the war sent home fifty dollars to his intended, Miss Almada Georgiana Bottom, and told her she might *swell* for once, as she had never had a fair chance in life. The next Sunday I rather guess there was a sensation in the Hookertown Meeting House that kept sleepy folks awake, if the sermon didn't. She had on a pair of ear-rings, a big gold-washed watch-chain, and brace-lets like Col. Smith's daughter, a monstrous swell of hoop skirts, one of those two story bonnets with pink flowers in the second story and a top knot of feathers, and to top all, or rather to bottom all, a pair of new calf skin shoes that squeaked like a eider mill. She came sailing in to meeting just after the first hymn, when Mr. Spooner was reading scripture where it says "Behold the lilies of the field," etc. The shoes made such a squeaking that he had to stop until the young woman got seated. Some of the young folks in the pew behind me tittered, and an old lady in my own pew put a handkerchief to her mouth. I suppose she wanted to cough just then, and didn't like to disturb the meeting. Mr. Spooner looked astonished, as if he had seen a vision.

Now you see this sort of thing is going on all over the country, and there is a good deal of extravagance in folks buying jewelry and knick-knacks that they do not have any use for. I suppose it is rather worse than common just now, but there has always been a good deal of it. If a man buys what he don't need, I call him extravagant, whether it is an extra acre of land, a two story bonnet, or a bogus gold watch chain, without any watch. If a man can do his business with a wheel barrow, he should not invest in a horse and cart. If his farm only affords occupation for one horse and cart, he should not buy a yoke of oxen and cart. If he has only capital to work twenty acres to advantage, he is very extravagant to purchase fifty. If he has only feed for six cows, he should not keep eight. This is one of our greatest faults as a people, and I am afraid this war, if it ends in the triumph of the government, as we hope it will, will not remedy the evil. We buy cargoes of silks, and jewelry, wines, and brandies, that we have no need of. Miss Almada Georgiana Bottom is not the only sinner among us, not by many a hundred, I tell you.

Hookertown, } Yours to command,
Jan. 1st, 1863. } TIMOTHY BUNKER, Esq.

Adulterations.

Many of the articles in common use in families are subject to fraudulent mixture, especially those which are sold in the ground or powdered state. Ground spices are, from their high price, not only adulterated with other substances, but inferior and damaged articles, such as could not be sold in the whole condition, are made into powder. The additions made to spices are not generally of a deleterious nature, but are simply a fraud upon the buyer, who gets much less of the real article than he pays for. Old ship biscuit and Indian meal flour, and ground oil cake are among the substances used, and tons of these are annually sold at the price of spices. The value of spices depends upon the oil they contain, in some instances the oil of cloves and cinnamon is previously extracted and the articles afterwards ground and sold. We have known a wholesale dealer to keep three sorts of ground ginger, which he sold to retailers at as many different prices, under the names of fresh, pure and extra. These differed only in the proportions of meal they contained. It is very difficult to find pure ground mustards; much of that in the market contains very little of the flour of mustard seed, and a great deal of the flour of wheat, with turmeric to give a fine yellow color. Having occasion some time ago to make use of a mustard poultice, we were obliged to make four trials, with mustard bought at different places, before we could find any which would produce any redness of the skin, or even a feeling of warmth. Cayenne pepper, which, from being troublesome to prepare, is usually bought ready ground, is much adulterated. This is often mixed with harmless substances, but sometimes red lead, which is poisonous, is used to bring up the color. Pure Cayenne is of an orange red color; any which is bright red or scarlet should be looked upon with suspicion. Where a spice is much adulterated the lack of proper taste and smell will detect it—but such pungent articles can be mixed with tasteless materials to a considerable extent without materially altering the taste or smell. Adulterations can be readily detected by the microscope, but there are few who have the skill and the means to make the examination, and the only safe way is to purchase the articles unground, and pound or grind them in the house.

Beans and Peas as Food—Hints on Cooking Them.

We suspect that economical housekeepers are not generally aware of the value of beans and peas as a source of nourishment, or these articles would be more freely consumed. They are similar in composition, both containing a large proportion of nitrogenous compounds, which supply direct nutriment to the muscles of the body. In fact, they furnish the most concentrated form of strength imparting vegetable nourishment. Travelers over the eastern deserts, who have occasion to carry the greatest amount of life sustaining food in the least weight, take with them the roasted chick-peas, which are similar in composition to our common beans and peas. The Chinese prepare a cheese from peas, which is quite like a milk cheese. The peas are boiled to a thin paste, strained through a sieve, and the curd obtained after coagulation is treated like that from milk. Beans and peas are by some considered to be difficult of digestion, and constipating. The constipating property is probably due to the fact that nearly all the substance is converted into nutriment, leaving little solid waste material to excite and produce evacuations of the intestines. This can be corrected by eating coarse and bulky food with them. The difficulty of digestion is due mainly, we think, to the method of cooking too often practiced. The skin of the kernels is almost absolutely impenetrable to the gastric juice of the stomach. If the skins be not thoroughly broken in cooking, or in eating, the gastric fluid can not do its work, and heartburn or pain in the stomach is the result; while

the undigested kernels or parts of kernels pass into the intestines, and by fermentation these produce gas, leading to flatulence (colic). Let the beans or peas be so thoroughly cooked as to form a soft, mushy mass, and they will be easily digested, and the evils above referred to, will be obviated. A very common process is to boil them for a time, and then complete the cooking by baking them with pork. They are then dry, and the skin mainly unbroken, except slight cracks or checks upon one side, and being coated with baked lard, they are in the worst possible condition to be easily transformed into nourishment in the stomach. Baked "pork and beans" is with some a favorite dish, and those having the "stomach of an ostrich" can manage to digest a considerable portion of this material, especially if they take the time to chew it finely before swallowing; but as a rule, for children and those having but an ordinarily good digestion, it is best to leave out the pork. Beans are abundantly rich themselves, without the addition of baked or boiled pork fat. The best mode of cooking is, to boil them, in soft water only, to a mushy condition, so that the skin shall be thoroughly broken up. A piece of lean meat may be boiled with them to change the flavor, if desired, though good beans in a well cooked soft state, have a rich butter-like taste of themselves, without any addition except salt. Soft water is essential to the good cooking of beans. Pea soup is about equally nutritious with that made from beans, and their frequent use will render them palatable.

Hints on Cooking, etc.

Good Breakfast Cakes.—Mrs. M. Hollingsworth, Armstrong Co., Pa., contributes the following to the *American Agriculturist*: Take equal parts of wheat flour, buckwheat, and corn meal sifted, enough to make a batter with 1 pint skim milk (sweet), 1 pint sour milk, or buttermilk, 1 egg, 1 teaspoonful each of salt and cooking soda. Bake and serve up the same as buckwheat cakes.

Griddle Cakes.—Preferred to buckwheat by the contributor, O. B. Fenner, Marion Co., Ill. 1 gill of good yeast, $\frac{1}{2}$ teaspoonful of salt, 1 qt. of blood warm water, 1 cup of Indian meal, $1\frac{1}{2}$ cups of rye meal. Thicken with flour. Let the Indian and rye meal be sifted through a coarse sieve; mix at night for the next morning's use, and set in a place warm enough for them to rise. In the morning they will be exceedingly light and spongy; then add about 1 teaspoonful of saleratus, or enough to make them sweet; (a little smart taste before frying is not disagreeable or hurtful). Fry on a hot griddle, and eat as soon as fried.

Corn and Pumpkin Bread.—Mrs. Rhoda C. Whitford, Addison Co., Vt., contributes the following to the *American Agriculturist*. Take 3 quarts of corn meal, and pour on boiling water enough to scald it. Add 3 pints of stewed pumpkin (cheese pumpkin is best), 3 pints coarse wheat flour, buttermilk or sour milk enough to make soft dough, and 2 teaspoonfuls saleratus. Bake 3 hours.

Saratoga Rolls.—Contributed to the *American Agriculturist*, by A. B. Shattuck, Chataqua Co., N. Y.: Take 1 pint sweet milk, 2 pints flour, 2 tablespoonfuls butter, 4 tablespoonfuls yeast, and $\frac{1}{2}$ teaspoonful saleratus. Beat thoroughly and let it rise 5 or 6 hours, or all night, if for breakfast. Pour in a shallow pan and bake half an hour.

Hints on Making Tarts.—"Vermont Subscriber" in a letter to the *American Agriculturist* about seeds, adds: "My wife saves trouble and patience, things that ought to be saved, thus: Instead of cutting out bottom pieces of dough, and then sticking on an edging or rim that often comes off, she puts the round piece of dough into a small scalloped tin plate, about three inches across at the top. The dough bended up at the sides for half an inch forms a nice edging. If the dough be rich in shortening, no greasing of the tin will be needed."

Sausage Recipes.—E. Dexter, Windham Co., Conn., sends the following, which he says is pronounced excellent by those who have tried it:

To 100 lbs. of meat add 9 teacups of salt, 5 teacups sage, 3 teacups pepper, 2 teacups summer savory, and 1 teacup of ginger. After mixing thoroughly, pack closely in tin pans, make the surface smooth, and cover with melted lard to the depth of $\frac{1}{4}$ inch. By thus excluding the air it will keep for several months as fresh as when first made.

The above directions appear to us to be too *spicy* and not sufficiently definite. The pepper and sage should suffice, we think, without the summer savory and ginger. However, tastes differ, and the mixture may suit many. The amounts of ingredients should always be stated in pounds and oz.: some teacups contain nearly twice as much as others. The following proportions for sausages were furnished at our request by Mr. W. H. Cady, Columbia Co., N. Y., one of the best sausage-makers that ever supplied the writer's table. They are: 40 oz. salt, 8 to 10 oz. pepper (according to taste), and 8 oz. sage, to every 100 lbs. meat. *

Superior Pudding.—Contributed to the *American Agriculturist*, by Mrs. E. E. Vedder, Marquette Co., Wis. Boil two quarts of milk; rub one egg in flour sufficient to make it dry enough to rub through a sieve. Stir the egg and flour in the boiling milk; cool, and add four eggs well beaten, and one tablespoonful of sugar. Bake the same as custard. Serve with a sauce of butter and sugar well beaten; use any flavoring desired.

Pepper on Salt Pork.—A subscriber writes: After a layer is packed, with an oak stave press the pork from the side of the barrel and fill the space with salt. On every layer put fine ground black pepper enough to make the pork look black. Any person who tries this will never after omit it. [This may impart a better flavor to the meat, but the use of so much pepper is objectionable.—Ed.]

Stuffed Beef Steak.—Pronounced superior, by the contributor of the directions for cooking it, Mrs. H. L. Johnson, New-Haven Co., Conn. Take a large round steak free from bone; make a dressing the same as for turkey, and spread it on the meat. Roll it up tightly, put it in a cloth and boil for one hour in just enough water to cover it.

Suet Pudding.—For competition with the Queen of Puddings, described in the December *Agriculturist*, page 372. Contributed by O. B. Fenner, Marion Co., Ill.: 1 cup of suet, 1 cup of molasses, 1 cup of raisins, 1 cup of sweet milk, 3 of flour, $\frac{1}{2}$ teaspoonful of saleratus, and a little salt. Any spice added, the writer thinks wasted, but others can spice to their taste. After mixing, place the pudding in a tight tin kettle, set the latter in a boiler, and steam from 3 to 4 hours.

Waffles.—1 qt. of sweet milk, 2 eggs, $\frac{1}{2}$ teaspoonful of saleratus and a good pinch of salt. Thicken with flour to a batter. Bake in waffle irons.

Good Cough Medicine for Children.

We have little faith in "universal remedies," and seldom publish in the *American Agriculturist* either prescriptions or advertisements for medicines of any kind. What is one man's meat is often another's poison. In giving the following cough remedy, we therefore offer it only as one that for seven years has almost always proved effective in our own family. Put into a vial equal proportions by measure of *Syrup of Ipecac*, *Puregoric*, and *Castor oil*. Shake well together, and always shake before using. From half a teaspoonful to a full teaspoonful given to a child on going to bed, or at other times, usually checks coughing after a few minutes. If needed, the dose is repeated after three or four hours. It is well to begin with half a teaspoonful and increase the quantity if needed. The food should be light, or the syrup of ipecac may produce a little nausea.

"Figures won't lie," is an old and homely expression; yet few can look on a fashionable woman's figure now-a-days and say as much.

The coat of a horse is the gift of nature. That of many an ass is often the work of the tailor.

Beauty without virtue, is a flower without perfume.

LOOKING AT GRANDPA'S WATCH.

Engraved for the American Agriculturist.

The Editor with his Young Readers.**About the Picture.**

Which is the happier, the child or his grandfather? The watch is a greater wonder to the little fellow than all the curiosities of the Museum would be to older persons. With what delight he looks at the shining wheels, and listens to the tick-tick which make it appear like a living thing. But that is not the whole of his pleasure. Notice the hand on the old gentleman's shoulder, showing the arm affectionately thrown around his neck, saying as plainly as words could do, "I love Grandpa." See too, how earnestly the grandfather is looking at the watch. He has seen it a thousand times, why is he so interested? He loves the little one so much that he partakes of the child's feelings, he sympathizes in his joy. Every girl and boy looking at this beautiful picture will feel like saying, "What a dear old man." Although his features are sharpened by age, love makes him beautiful, makes him happy, and it is a pleasure to look upon him. And right here is the secret of the brightest charm of life, for the young and for the old. Selfishness spoils the heart, disfigures the face, and ruins peace; kindness, affection, love, are sources of constant joy to the possessor as well as to those about him; they give beauty to the spirit, which will outshine and outlast every other attraction.

A Harmless Monster.

A young lad of our acquaintance was one day weeding in the garden. The weather was very warm, and he wore neither coat nor vest. He was very busy over a bed of carrots, that is, his fingers were, his thoughts were full of something else, as you could see by his steady and almost vacant stare. But suddenly he gave a startling scream, sprang from his sitting position, threw his hand

wildly over his shoulder, and writhed and twisted as though striving to escape from the hold of some terrible monster. His countenance was ghastly with the agony of fear. The writer sprang to his relief, and found him grasping something which had made its way to his shoulder, under his shirt. Could it be a snake, or a rat? The collar was quickly loosened and the fearful thing came to light. It was a large grasshopper! From that time to the present, that boy, who is now a man, has made it a rule to first see if there were danger, before losing his wits from causeless fear. A very good resolution for all; he who can keep it will be likely to keep his wits also.

A Cat giving away her Kitten.

We have known instances where parents have given away their children that they might be better provided for, but this is the first time we have heard of such a proceeding among animals. A correspondent vouches for the truth of the following incident which he says occurred in the family of one of the subscribers of the *American Agriculturist*. Mr. B. had two cats, both long domesticated in the house. A short time since each had kittens. The owner wished to rear one kitten at the barn that it might keep the rats and mice within bounds. He therefore took one cat with one kitten (having killed the others of her family), and made a nest for them at the barn, where they staid for a while quite contentedly. One night there occurred a very hard storm of wind and rain. The next morning, as soon as the family were up, the cat brought the kitten to the house, apparently half drowned, and placed it in a box containing the other family of kittens, refusing ever after to have any thing to do with it. The children placed it time and again by its mother, and every means were tried to induce her to take to it again, but without avail. The other cat, among whose kittens it

was placed, received it kindly into her family, and nursed and brought it up as though it had been one of her own litter.

A Young Editor.

It is very seldom that room can be spared in the *Agriculturist*, to speak of the books, magazines, etc., which publishers often send to us for examination; all the space is wanted for what will interest our readers more. But here is a magazine just received from Portland, Maine, about which we must say a few words. Its name is "King's Lady's Book." It is about five inches long, and three inches wide, contains eight pages, besides a neatly printed cover, and is published monthly at twenty-five cents a year. Its editor is nearly eight years old. His father informs us that the lad selects his own articles, and sets up the types on which they are printed. We believe him to be the youngest member of the profession, and extend to him the right hand of fellowship. We hope that his arduous duties will not impair his health, nor stop his growth. Let his parents take care that his mind be not developed at the expense of his body, which too often occurs with children. Now, for some of you boys, and girls too, from twelve to fifteen or more years old, it will be a capital thing to commence issuing such a paper in your own neighborhood. It is not necessary to print it. Write it out on foolscap paper. Get your school-mates to contribute to it, and come together once a week to hear it read. Several journals of this kind were started among our young friends a few years ago, after reading the advice then given, for them to have their own newspaper. Perhaps such an enterprise will be the first step toward raising up a future editor of the *Agriculturist*. If so, he will be all the more capable for having commenced young.

Another Perfumery Story.

A correspondent at Racine, Wis., after reading the story of "The Horrified Dandy," in the November *Agriculturist*, contributes the following "of the same sort" which he says actually occurred. When "boarding round" was the fashion with school teachers, farmer A, on coming to the house at tea time, was introduced to the "school ma'am." In a moment he perceived a strong odor of musk which came from the school ma'am's clothing. He, entirely ignorant of the cause, immediately charged it on Ponto, who had a strong propensity for hunting muskrats, and at once commanded him: "Ponto, you scamp, you have been killing muskrats; go out doors, sir, and get sweetened off." But Ponto did not stir, and Farmer A spoke again more sharply. "Get out, you'll scent the whole house." The school ma'am by this time was blushing red as crimson, while the girls and the boys could scarcely keep from bursting into laughter. One of them, unnoticed, at last made their father understand how the matter stood, and he, of course, dropped the subject. The evening passed away rather awkwardly with all, and the teacher failed to return the next day. On her account, the affair was kept quiet until after she left the neighborhood, when many were the hearty laughs had over farmer A's error and the schoolma'am's discomfiture. She omitted musk thereafter.

Learn to Control the Voice.

To keep the lungs and the voice in good condition, it is necessary to give them plenty of exercise. This is doubtless one reason why it is so natural for young people to laugh, shout, and sing. The Creator intended that their vocal organs should be well developed in youth, and so it is found almost impossible to keep a child quiet long at a time. But, boys and girls, you who are old enough to think about the matter, do not let this natural impulse make your company unpleasant to older persons. Let the playground, or the fields, ring with your happy shouts; there is plenty of room for noise there, and it will do you good, but in the house, learn to speak quietly. Keep the voice down to a pleasant tone. Loud words are very annoying to a tired or nervous person. Fathers and mothers would be "cross" much less frequently, and children happier, if this rule were generally observed; practice would very soon make it a habit.

The Game of Initials.

R. F. Roberts, Racine Co., Wis., writes to the *American Agriculturist*: "I used, when a boy, to think the following game was very interesting and somewhat instructive, and indeed have joined in it since I attained my 21st year. One of the company selects the name of some animal, reptile, fish, or insect, and gives the initial letter, mentioning to which class it belongs; the company to guess the name. For instance: "P, in birds." Those guessing, give the name of the birds they think of whose names commence with P; as pigeon, pelican, peacock, partridge, etc. The one who gives the right answer proposes the next question. Of course those names are selected which are supposed to be least known. I recollect once the initials G. W. T., in birds, were proposed, and the whole company had to give it up. The name may not be in the books, but the bird is so known to hunters in the West. Can any of your boys or girls name it? [It would add very much to the instructiveness of this game to require the questioner to give a few particulars of the habits, locality, etc., of the bird whose initials he selects.—Ed.]

The Roll of Honor.

A year ago we published a series of 52 Bible Lessons averaging about $7\frac{1}{2}$ verses each, or 394 verses in all. Our young readers were invited to commit them to memory, and we promised to publish in this paper the names of those whose teachers or parents should send a statement that they had learned them all, and recited them during December. Printing paper being too high to allow of a supplement, we omitted calling for the names during the last two months. But many remembered our promise, and the following 53 names have been sent in as having accomplished the task. (Many others have written that the lessons were learned, but were not repeated together, and so the names were not sent. Indeed, we have heard of hundreds who learned nearly all the lessons, and probably thousands of others have done so.) Here is the

ROLL OF HONOR.

Name.	County.	State.
ABIGAIL V. YOUNG.....	Cape May,	New-Jersey.
ALEXANDER THOMPSON.....	Orange,	New-York.
AMANDA KINO.....	Saratoga,	New-York.
ANGELINE CARTER.....	Clay,	Indiana.
ANNE WADE.....	Oregon.
ANNIE EMELIE COLE.....	Bristol,	Rhode-Island.
ARISTIDES MILLS.....	Crawford,	Wisconsin.
AUGUSTUS THOMPSON JR.....	Orange,	New-York.
BARTLETT C. CHURCH.....	Cheshire,	New-Hampshire.
CHARLES C. STUART.....	New-York,	New-York.
CHARLES E. PINNEY.....	Addison,	Vermont.
CHARLES FARQUHAR.....	Address not given.
CHARLOTTE GOEBLE.....	Kings,	New-York.
ELIZABETH C. TROTT.....	Niagara,	New-York.
ELIZA M. SHERWOOD.....	Fairfield,	Connecticut.
ELIZA WEST.....	Canada West.
EMILY HEALY.....	Rock-Island,	Illinois.
EMMA C. HOMAN.....	Queens,	New-York.
EMMA JANE CARPENTER.....	Queens,	New-York.
EMMA JANE FRENCH.....	Queens,	New-York.
ERMINA N. EDWARDS.....	Fairfield,	Connecticut.
FANNIE MORTON.....	Queens,	New-York.
FANNIE WHITE.....	Queens,	New-York.
FREDDIE W. SMITH.....	New-Haven,	Connecticut.
GEORGE C. DICKERSON.....	Kings,	New-York.
GEORGE H. THOMPSON.....	Orange,	New-York.
GEORGE ROBINSON.....	Address not given.
GILBERT C. H. STILES.....	Queens,	New-York.
HATTIE M. MONTOMERY.....	Jefferson,	Wisconsin.
IRVING HOAGLAND.....	Warren,	New-Jersey.
JENNIE K. CUNNINGHAM.....	Adams,	Pennsylvania.
JENNIE BUCKLEU.....	Cayuga,	New-York.
JOHN F. BELL.....	Kent,	Delaware.
JOSEPH C. FULLER.....	Pierce,	Wisconsin.
LIZZIE S. CUNNINGHAM.....	Adams,	Pennsylvania.
LUCRETIA E. DANIELSON.....	Rockingham,	New-Hampshire.
MARGARET DJICKIE.....	Perth,	Canada West.
MARY E. LAWRENCE.....	Queens,	New-York.
MARY G. PEASE.....	St. Lawrence,	New-York.
MARY LAMB.....	Louisa,	Iowa.
MARY MORTON.....	Queens,	New-York.
ROBERT MATTHEWS.....	Randolph,	Illinois.
RUSSELL D. MARTIN.....	Cattaraugus,	New-York.
SARAH FORD JUDD.....	Queens,	New-York.
SARAH JANE UDALL.....	Niagara,	New-York.
SELINA J. ROBINSON.....	Address not given.
SOPHIA C. GIDDINGS.....	Dutchess,	New-York.
SUSAN BUCKBEE.....	Queens,	New-York.
SUSIE H. THOMPSON.....	Orange,	New-York.
THEO. I. KINO.....	Cumberland,	Maine.
WILBUR S. EDWARDS.....	Fairfield,	Connecticut.
WM. H. EUSTIS.....	Jefferson,	New-York.
WM. ORANGE JUDD.....	Queens,	New-York.

A Remarkable Bouquet.

The above engraving looks, at first sight, simply like an ordinary bunch of violets, but those who have learned to use their eyes properly, may discover something more. In the group of flowers are contained profile likenesses of Napoleon I, his wife Maria Louisa, and of Napoleon II. To find them, examine each leaf, carefully: when once seen, they will appear so plainly, the wonder will be that they were not discovered at the first look. It is said that after the banishment of Napoleon and the restoration of the Bourbons to the throne, it was forbidden by law to exhibit the portraits of Napoleon or his family, but an ingenious Frenchman, who loved Napoleon, devised this method of presenting the desired likenesses without much fear of detection. Thousands of them were readily sold in France.

A Musical Horse.

The Genesee Farmer gives, at considerable length, a good story of a musical horse, which we condense for the young readers of the *American Agriculturist*. The horse was named Fib. She was a powerful animal, rather lazy, and occasionally balky, for which she had been beaten and tortured many times without effect. When she chose not to go, not a step would she stir, until at last they ceased trying to conquer her with force. It was noticed that Fib worked well in clear weather, but when it was damp and oppressive, she was almost sure to balk. At last a novel way was found to start her. One hot day in harvest, when a shower was rapidly coming, the last load was on the wagon, and all was going smoothly; but about ten rods from the barn, Fib stopped short. The men were furious, and would have beaten her cruelly, but her owner stopped them and called on the driver, who was a capital singer to strike up a tune. He immediately commenced a Methodist hymn, two lines of which had a ringing chorus. The shower drew nearer. "Sing away," cried the owner, "sing away Hart, the old hag is relenting, I see it in her eye, and the tips of her ear are playing to your music like a lady's fingers on the guitar." Sure enough, in a moment more off she started, and the load was safely housed just as the rain commenced falling. After this a Methodist hymn would always start her, and Hart declared that Fib knew a Methodist hymn from any other, but this was merely his imagination.

The Enraged Musician.

Handel the great German Musician was a very nervous, irritable man, and like most musicians, particularly sensitive where music of his own composition was concerned. It is related that on one occasion he wished to have one of his great pieces performed in a country village, and inquired if there were any musicians to be had. A large number were recommended as particularly skillful, and he at once sent for them—"Can you read music?" asked Handel, when they were assembled. "Yes sir," "certainly," was answered from all parts of the room. "We play in the church," remarked one old gentleman who had brought his bass-viol. "Well then," said Handel, "let me hear you play that," at the same time distributing the manuscripts on which were written the musical notes.

After giving them a few instructions as to their various parts, he retired to a distant corner of the room to listen to the effect. They commenced playing, but were soon puzzled, and made most outrageous discords. Handel sprang from his seat in a rage, and rushing furiously toward the frightened old gentleman with the bass-viol exclaimed: "You play in the church—very well, you may play in the church, for we read the Lord is long suffering, of great kindness, forgiving iniquity, transgression and sin; you shall play in the church, but you shall not play for me;" and gathering up his manuscripts he rushed furiously from the room. *

Curious Sentence.

It requires no little ingenuity to make a sentence which shall be the same when read either forward or backward. There are a few such in English, but here is one from the Latin language which is ahead of any thing we have met with elsewhere. "Sator arepo tenet opra roas." The words are the same at whichever end you commence: but there is something about it more curious still. Arrange the words, one under another thus: Now the sentence reads the same S A T O R by beginning at the top of A R E P O the first column and going T E N E T downward, or by beginning O P E R A at the bottom of the last R O T A S

column and reading upward. The author of this singular arrangement must have spent time enough upon it to have written at least a number of the *Agriculturist*. Who can tell what the words of the sentence mean? *

A soliloquising schoolmaster, being asked why he talked so much to himself, replied: "In the first place I like to talk to a sensible man; and in the second place I like to hear a sensible man talk." Two very good reasons.

Problems and Puzzles.

No. 28. *Arithmetical Problem*.—"J. D. M." Hudson, N. Y., contributes the following, which, though not intricate, will give good exercise in careful figuring: "In what time would a bond of \$1000 be liquidated by paying \$80 a year, interest being 7 per cent. per annum.

No. 29. *Cent Puzzle*.—Find on the head of a new cent, a fruit; flowers; a house of worship; an animal; a quantity of grain; and a protection against thieves.

No. 30.—*Transposition*.—O. F. Kinstey, Welland Co., C. W., asks "How to make one word out of the two words new door."

No. 31. *Illustrated Rebus*.—An excellent motto.

Answers to Puzzles and Problems in January No. (page 25). *Picture Puzzles*: No. 24, Fig. 1 represents an economical man, because he is trying to make both ends meet. No. 25, Fig. 2, represents an enterprising business firm, because both are trying to get a-head; it also is like a fortress, because it shows a strong-hold.

Riddle, No. 26: The answer is a pen.

Illustrated Rebus, No. 27, reads: S teading a in s in small t h in g s in c rease wealth m ower than watch in g and weight in g four sum great t h in g. That is: Steady gains in small things increase wealth more than watching and waiting for some great thing.

The following have sent in correct answers up to the date of January 16th; viz.: Alice P. Talbot, 20; Edmund J. Young, 21, 22, 23; Thos. S. Peck, 20, 22, 23; W. S. Van Meter, 20; Dewitt C. Chailles, 20, 22, 23; "T. B.", 26; "J. D. M.", 20, 22, 23; H. K. Morrell, 27 (nearly); "Georgius Rex," 21, 25, 26, 27; John Tempest, 20; J. McKinstry, 27 (nearly); Elbert M. Swan, 24; Miss E. W. A., 27; C. J. Shryvers 24, 25, 26; E. W. Jones, 27.

Seeds for Free Distribution to all Subscribers for 1863 (Vol. 22.)

See Descriptive Notes last month, page 4.

Every subscriber to the *Agriculturist* for 1863, is invited to select **three or four parcels** of seeds from the list below, if he can not get them conveniently otherwise.

These seeds are all valuable. Of the 63 kinds offered, many are comparatively new varieties, but we include some common, useful sorts for the convenience of those without access even to common good seeds.

Most of them are annuals (reproducing seed the first season), and in all cases there will be enough to yield a supply of seed for future use. Our aim is, to furnish the *germs* of future abundance in each locality where these seeds go.

Many of these seeds were grown by ourselves, the past year; the others are obtained of the best growers. The distribution will begin in February.

Mode of Distribution.—The seeds may be called for at the office, after March 1, or be applied for by mail at any time now, to be forwarded as soon as ready. The postage is only **1 cent per ounce under 1500 miles; and 2 cents per ounce when over 1500 miles.**

Those sending for seeds to be forwarded by mail, will please carefully observe the following

DIRECTIONS.—(1) Select from the list below, any **three or four** parcels desired, and write **plainly** on a slip of paper the **numbers** (only) of the kinds of seeds wanted. (These numbers are used on our seed drawers, seed bags, etc.)

(2) Enclose the slip in a prepared envelope—directed in full to **your own address** (not John Smith's), and put on it postage stamps to the amount of **one cent for each ounce of seeds to be enclosed, if to go under 1500 miles, or two cents if to go over 1500 miles.** (Most places West of the Mississippi river are over 1500 miles.) **N.B.**—The total amount of stamps required can be reckoned from the table of seeds below. Any fraction over even ounces will need an extra 1-c. or two 1-cent stamps according to distance. Forward the above prepared envelopes to this office, in a letter, and the seeds will be enclosed according to the numbers on the slip. To save postage, let there be **no marks on the envelopes** except the address and stamps. About 2 ounces will go in a common sized envelope.

John Smith,
Albion,
Monroe County,
Iowa.

Field, and Vegetable Garden Seeds.

No.	Weight of package.
151—Mammoth M. Lett.	About one-half ounce.
152—Darling's Early Sweet Corn.	About one ounce.
153—Stowell's Evergreen Sweet Corn.	About one ounce.
157—Conn. Broad Leaf Tobacco.	Less than one-eighth ounce.
158—Genuine Havana Tobacco.	Less than one-eighth ounce.
8—Daniel O'Rourke Pea.	About one ounce.
9—Champion of England Pea.	About one ounce.
12—Green Kohi Rabi.	About one-fourth ounce.
115—Flat Dutch (Winter) Cabbage.	About one-fourth ounce.
218—Early Sugar Leaf Cabbage.	About one-fourth ounce.
199—Red Dutch Cabbage.	About one-fourth ounce.
62—Extra early Round Turnip Radish.	One-fourth ounce.
19—Round Spinach.	About one-half ounce.
147—Neapolitan Cabbage Lettuce.	About one-fourth ounce.
101—Improved Long Orange Carrot.	About one-half ounce.
149—Extra early Bassano Beet.	About one-half ounce.
55—Hubbard Squash, pure.	About one-fourth ounce.
193—Fejee & Italian Red Tomato.	About one-eighth ounce.
154—Ice Cream Water Melon.	About one-eighth ounce.
217—Fine Nutmeg Melon.	About one-eighth ounce.
141—Hollow Crown Parsnip.	About one-fourth ounce.
152—Fine Large Cheese Pumpkin.	About one-fourth ounce.
17—Red Strap Leaf Turnip.	About one-fourth ounce.
195—Early Short Horn Carrot.	About one-fourth ounce.
196—Green Curled Kale.	About one-fourth ounce.
100—Improved Purple Egg Plant.	About one-half ounce.
197—Linnaeus Rhubarb.	About one-half ounce.

Flower and Ornamental Seeds.

89—Cotton Plant (2 kinds, mixed).	One-half ounce.
111—Castor Oil Bean.	One-half ounce.
On an average any five of the following varieties will go under one 1-cent stamp, (or two stamps if over 1500 miles.)	
200—Fancy Gourds, (mixed varieties) (ha)	203—Mixed G'n Poppy, (ha)
23—Mignonette, (ha)	204—Mixed F'n Poppy, (ha)
30—Tassel Flower, (ha)	205—Double French Marigold, (ha)
31—Chinese Pink, (ha)	206—Golden Straw Flower, (everlasting) (ha)
37—Beautiful Zinnias, (mixed) (ha)	210—Convulvulus minor, (ha)
49—Candytuft, (ha)	212—Fine Sweet Peas, (ha)
51—Drummond's Phlox, (ha)	219—Martynia in var. (ha)
123—Gilia nivalis, (ha)	220—Perilla Nankinensis, (ha)
124—Whitlavia, (ha)	221—Striped Mirabilis, (ha)
126—Long tubed Centaurea, (ha)	222—Convulvulus variegatus, (ha)
164—Sweet-scented Ageratum, (ha)	216—Acroclinium roseum, (ha)
169—Clarkia pulchella, (ha)	122—Mixed Canterbury Bells, (ha)
173—Mixed Larkspur, (ha)	170—Evening Primrose, (hb)
177—Graceful Quaking Grass, (ha)	42—Foxglove, (hp)
182—Sweet Alyssum, (ha)	209—Dwarf Blue Larkspur, (hp)
183—Fine Mixed German Asters, (ha)	223—Mourning Bride, (hp)

* (ha), hardy annual; (hba), half hardy annual; (ta), tender annual; (hbb), half hardy biennial; (tb), tender biennial; (hpb), hardy perennial; (hhp), half hardy perennial; (tp), tender perennial.

Special to Canada Subscribers.—Owing to the fact that some Postmasters in the British Provinces insist upon collecting 20 cents an ounce on Seeds and Plants, prepaid here at the U. S. rates, it is hardly safe to send for seeds not worth that cost. Those living near the lines can usually have them mailed to some U. S. Post Office, where they can get them by private hands. Where clubs of considerable size are formed, it will pay to have seeds for all come together in a parcel by express.

New York Live Stock Trade for 1862.

The Live Stock Markets of New York city are by far the largest in this country. The importance of these markets is indicated by the fact that during last year, nearly **two millions** of live animals were brought here for slaughter. At the Forty-fourth street or Washington Yards alone, more than **two hundred thousand** (200,000) **beef cattle** were received and sold. The principal transactions are confined to a few points. **Beef cattle** are sold mainly at the Washington yards, kept by A. M. Allerton. These occupy the squares bounded east by Fourth avenue; west by Fifth avenue; south by Forty-third street; and north by Forty-sixth street. Lesser numbers are sold at Brownings and O'Brien's, on Sixth street, near Third avenue; at Chamberlin's on Robinson street, (nearly west of our office); and over the Hudson river at the Bergen yards, near the old terminus of the Erie Railroad. **Milk cows, sheep, and veal calves** are sold at all the four city markets. **Hogs** are mainly sold at West Fortieth street near the Hudson River.

At present the principal weekly market day for beef cattle is on Monday; the sales, however, are continued into Tuesday, the yards being generally cleaned out at about the middle of the afternoon of that day. **Veal calves** are mainly sold on Wednesdays. **Cows, sheep, and live hogs** are sold on all days, the largest transactions being on the first two days of the week, especially for sheep. A careful reporter, of long experience, from the office of the *American Agriculturist*, is always present at these sales, and with proper assistants, gathers up all items of interest, the number and derivation of the cattle, the number of other animals in, the prices realized, notes upon sales, etc., etc. These are furnished to some of the journals regularly, including the *Daily*, *Semi-weekly*, and *Weekly Times*, and the *Methodist*, and we also publish a condensed report for this Journal. Below is a summary for the past year, which will be found interesting, and useful for reference. Many of these figures we have already furnished to other journals.

WEEKLY AND TOTAL RECEIPTS FOR 1862.

Week ending	Beef Cattle.	Cows.	Milk Cows.	Veal Calves.	Sheep.	Live Hogs.	Total all kinds.

1860....	4360	133	772	9883	6,147	21,305

AVERAGE PRICE PER LB. FOR THE NET OR ESTIMATED DRESSED WEIGHT OF ALL THE BEEF CATTLE SOLD.
1862.....7 1/2 | 1861.....7 1/4 | 1860.....8 1/2.

The Supply and Prices.

BEEF CATTLE have run remarkably uniform during three years past. The receipts averaged 4360; then 4265, and last year, 4532 per week. The total receipts, however, were about 10,000 head more last year than in any previous year. The details in the table above, indicate the variations from week to week, and at different seasons, as well as the effect upon prices, of a larger or smaller supply.—The Prices have varied from 7c. to 8 1/2 cents per pound, for the estimated weight of dressed carcasses. This is the average of all sales in every week. The range has been from 4 1/2 c. to 11c. for the different grades. It will be noticed that for exactly the first half of the year, the average weekly rates were nearly always at 8c. or above; while for the second half they were always below 8c., except one week. The average of the weekly averages is 7 1/2 cents. As larger numbers were sold at the lower rates, the average of all the cattle sold has been at about 7 cents and 6 mills. Owing to the short, dry pastures last Summer, in many localities, and to the general advance in other commodities, it is believed that higher prices will prevail during 1863.

MILK COWS.—The receipts for 1862 were considerably less than during the previous two years, and until just at the close, the prices rated very low. The stringent laws against swill milk from distilleries, and the increased facilities for bringing milk from the country, have lessened the demand for cows at the city markets.

VEAL CALVES.—The number received in 1862, was smaller than for the two previous years. The prices ranged fully as high as in 1861.

SHEEP.—The receipts of sheep and lambs for 1862 were 51,636 head less than in 1861, and the markets have generally been unsupplied. This has resulted from the high price of wool, and the consequent increased attention to wool growing. Both mutton and pelts have been much higher than previously. Sheep for slaughter, and for farm purposes, are probably higher now than ever before.

LIVE HOGS.—These have come to this market for a year past, in numbers beyond all precedent. The closing of the Mississippi, the trouble in the southwestern borders of the great corn producing regions, and the scarcity of barrel makers at the West, have caused a large shipment of live hogs to this market. The receipts for 1862 reached **1,098,712**. Prices ruled very low during most of 1862, and until the cool packing weather came on.

ALL KINDS.—The total number of animals of all kinds received in this city at the regular yards during 1862, reached the enormous figures of **1,845,605**, or an average for each week of **35,492**.

Derivation of the Beef Cattle.

Of the 235,660 Beef Cattle brought here last year, 211,060 were yarded at the great 44th-street markets, and of these our reporters have gathered the origin so far as could be learned from personal inquiry among the drovers, and from the yard books. The following table shows where the cattle came from.

From	No. of Head.	From	No. of Head.
Illinois.....	103,729	Missouri.....	1,711
New York.....	35,640	Pennsylvania.....	1,585
Ohio.....	19,705	Connecticut.....	569
Indiana.....	15,840	Canada.....	505
Kentucky.....	9,571	New-Jersey.....	427
Michigan.....	7,346	Virginia.....	117
Iowa.....	3,698		

It is noteworthy that of the 211,060 cattle at Forty-fourth street, 103,729, or nearly one half, are credited directly to the single State of Illinois! But more than this: of the 35,640 credited to New-York State, for example, a large proportion were raised and fed at the West, very many of them in Illinois, and brought on to be pastured awhile at the East. We may safely estimate, therefore, that to the single grazing and corn-growing State of Illinois, we are indebted for much more than half of the one hundred and sixty-five million pounds of beef brought to New-York during the year 1862!

RAILROADS AND LIVE STOCK.—The following table shows the routes by which the cattle yarded at Forty-fourth street have arrived here:

Hudson River R. R.	78,283	Camden & Amboy R. R.	1,844
Erie Railroad.	68,782	Hudson River Boats.	6,829
Harlem Railroad.....	43,996	On Foot.....	6,251
N. J. Central R. R.	11,728	New-Haven R. R.	148

The importance of our great railroads is illustrated by the receipts of Western stock, which form but a small item in their freight business. To say nothing of the million hogs and the half million sheep brought in mainly by railroad, at least 200,000 cattle have come in by cars. The curious in figures may estimate how long a line of cattle would be formed, were these cattle to be all driven here from the West, in one continuous drove: how many drovers would be required, how much feed on the way; how much the cattle would depreciate, etc., etc.

Market Review, Prices, Weather, etc.

Rye Flour, barrels.	1,867	865
Corn Meal, barrels.	16,560	14,711

We present above very carefully and laboriously prepared statistics of the trade in breadstuffs during 1862, with comparisons for the two preceding years, also comparative statements of the receipts, sales, and exports for the month ending to day, which included but twenty four business days, omitting Christmas and New Year's.

It will be seen (table 3) that the Receipts of flour at New-York City in 1862 exceeded those of 1861 by 788,637 barrels, which is equivalent to 3,943,155 (or nearly four

million) bushels of wheat. The receipts of wheat in the same time decreased 1,349,875 bushels, which still left an excess for 1862, of 2,593,309 bushels over the previous year.

The receipts of wheat at Chicago (table 7) last year fell off from those of 1861 by 4,402,376 bushels. This was partly counterbalanced by an excess in flour equivalent to 1,545,605 bushels, but still leaving a decline of 2,856,771 bushels in 1862.

The exports from New-York, (table 4) in 1862 as compared with 1861, show a decrease of 118,828 barrels of flour, and 3,333,559 bushels of wheat, or reducing flour to wheat, a decrease of 3,977,699 bushels of wheat.

The Stocks of Flour and Wheat on hand in New-York, (tables 5 and 6) are considerably larger Jan. 1st, 1863 at the same date, than in any of the preceding three years.

Similar comparisons may be made with respect to Corn, Rye, etc., but all the tables are so arranged as to show at a glance the condition of the breadstuff trade, and we hardly need repeat the items further.

During the past month, the breadstuff trade has been almost wholly governed by the rise and fall in gold, the higher currency rates in gold increasing the value of flour and grain for export. As shown in the table of "Current Wholesale Prices," the closing prices are considerably above the quotations in our last report (Dec. 18.). Holders are now quite firm, under the expectation of further advance. This will depend wholly upon the price of gold. Any financial schemes or changes reducing the relative values of gold and currency, will have a corresponding effect upon breadstuffs, so far as the latter are not influenced by other circumstances—foreign demand, etc. Provisions, especially hog products, have been in brisk demand, partly for export, and have advanced in price... Cotton, Wool, Hay, Hops, and Tobacco, have been more freely purchased at buoyant prices.... Heavier sales of other articles of general merchandise have also been effected. The table of Prices will show both present values and changes since last month.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have not been so well supplied during the past month as previously, the average being only 4,506 per week, or less than for any previous month since August, but larger than usual. Prices have advanced 1/2 c. during the past two weeks. This week's averages are not yet made up; at the last general market, Jan. 13th,

with 4663 head offered, a few extra fat cattle brought prices equivalent to 11 c. @ 11 1/2 c. per lb. for the dressed quarters; prime steers 9 1/2 c. @ 10 c.; fair beefs 8 1/2 c., poor 6 1/2 c. @ 7 1/2 c., average of all sales 8 c. Cattle are now selling well, with a prospect of good prices during the Winter.

Veal Calves.—Receipts have averaged 370 per week since our last report. They sell readily, a few choice ones at 3 1/2 c. per lb. live weight, but mostly at 6c. for good veals, and 5c. @ 5 1/2 c. for ordinary to fair calves.

Sheep and Lambs.—Receipts are falling off rapidly. The average weekly receipts have been only 6,301 during the past month, against over 10,000 for the preceding 4 weeks. Farmers and graziers are holding them back on account of the high prices of wool which make sheep raising one of the most profitable operations of the farm. Skins alone are worth \$2.37 @ \$2.50 in lots, while large selected pelts sometimes sell for \$3.00 each. The short supply in market has caused a rise in the price of sheep equal to 1c. per lb. Good sheep that will weigh 100 lbs. alive, are worth \$6 1/4 @ \$6 3/4 each. A mixed lot of 1000 head averaged \$6.55. Ordinary sheep sell at prices equivalent to 5 1/2 c. @ 6c. per lb. live weight.

Live Hogs—Receipts have averaged 44,120 per week, which is nearly equal to last month. For the week ending Dec. 30, no less than 61,165 live and several thousand dead hogs were received in the city and completely glutted the market, carrying prices down to 4 1/2 c. per lb., live weight, for prime corn-fed hogs. Prices have since recovered 1/2 c. being now 5c. @ 5 1/2 c. for fat corn-fed, 4 1/2 c. for medium, and 3 1/2 c. @ 4c. for distillery-fed hogs. Western mast, or nut fed hogs are worth only 3c. @ 3 1/2 c., being disliked by packers. The average weekly receipts of hogs last year was 21,129 against 11,292 for the year 1861.

The Weather has been remarkable for the season of the year. We have had very few cold days, and not over an inch of snow. The ground has been open most of the time, and farming operations have been carried on to an unusual extent. Fears are entertained that the warm weather followed by sudden freezings without the protection of a snowy covering, has injured the winter wheat and rye.—OUR DAILY NOTES CONDENSED, read: December 20, clear, cool, the thermometer at 9° in the evening and 4° the morning of the 21st, which was a clear day, with a light snow fall at night—22 cloudy, cool—23, 24, clear, mild—25, cloudy—26, cloudy, light rain at night—27, 28, 29, clear, warm—30, clear A. M., cloudy P. M., rain and snow at night—31, N.E. snow storm, mingled with rain, 1 inch snow remained on the ground—January 1, 2, 3, clear and moderating—snow gone—4, fog A. M., clear P. M.—5, clear, warm—6, fog, rain at night—7, cooler with snow squalls—8, clear, fine—9, cloudy—10, N.E. rain, and at night—11, 12 clear mild—13, cloudy—14, heavy rain at night—15, N.E. rain and heavy fog—16, continued rain—17, 18, 19, clear, cold.

The Rain Fall and melted snow, for month ending Jan. 15, amounts to 3.11 inches. The rise and fall of the Barometer has made a crooked path on our recording paper during the month. The range has been from 29.18 to 30.50 inches, rising and falling rapidly, in some cases over an inch in 24 hours.

Thermometer at 6 A. M., New-York.
[Observations carefully made upon a standard Thermometer (Fahrenheit).—Indicates rain—s, snow.]

It is hard for the Publisher to alone bear all the losses arising from the carelessness or oversight of the 20,000 Postmasters and carriers who have the handling of the *Agriculturist* between the office and the subscribers. But since Uncle Samuel monopolizes the carrying business, and won't stand any losses, and we can't compel him to, we shall cheerfully send a second copy of any number when the first one mailed, fails to reach its proper destination, on being notified of the fact. Numbers received and lost or spoiled will be forwarded at 10 cents each.

Circulation of the Agriculturist.

Beyond all doubt or controversy, the circulation of the American Agriculturist to regular subscribers, is many thousands greater than that of any other Agricultural or Horticultural Journal in the World, no matter what its character, or time or place of issue. The publisher is ready at all times to substantiate this statement by comparing books.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.
TERMS—(invariably cash before insertion):
FOR THE ENGLISH EDITION ONLY.
Fifty cents per line of space for each insertion.
One whole column (145 lines), or more, \$60 per column.
Business Notices, Eighty cents per line of space.
FOR THE GERMAN EDITION ONLY.
Ten cents per line of space for each insertion.
One whole column (130 lines), or more, \$10 per column.
Business Notices, twenty cents a line.

Help Wanted.

A single man—American or Scotchman preferred—wanted to take charge of a farm. He must be a practical man of experience, industrious, and honest, able to read and write. Also a neat tidy woman who can cook, wash, make butter, &c. Address JOHN H. ROCHE, Mead's Basin, Passaic Co., N. J.

COUNTRY HOUSE WANTED IN THE STATE
OF New-York, within 39 miles of the City, for a charitable Institution. House must contain not less than 16 rooms, with from 8 to 12 acres of good land for gardening—wanted to hire, with the privilege of purchase in three years. Rent very moderate. Address "YORK," Station D., N. Y. City.

BUSINESS STAND FOR SALE.—One of the very best on the Delaware and Hudson Canal. Address Box 94, Ellenville, Ulster Co., N. Y.

NOW READY.

The First Part of Dr. SMUCKER'S History
OF THE
SOUTHERN REBELLION,
From its origin, giving a full and reliable account of all the Battles, Sieges, Engagements, &c., &c.
This is the only authentic HISTORY OF THE WAR now published, and will contain over 500 Octavo pages, illustrated with numerous fine steel plates, from original drawings, by that eminent artist, SAMUEL SARTAIN, Esq.
A few good agents wanted, to whom the largest commission will be paid.
Specimen copies sent on receipt of the price, \$2.50.
BRADLEY & CO.,
PUBLISHERS,
No. 66 North Fourth Street, Philadelphia, Pa.

The Cranberry and its Culture.
The Subscriber has issued a circular from the press, treating on the Cranberry and its Culture. Said Circular will give persons the proper information as to the commencement of the culture. He will take pleasure in forwarding them to all parts of the United States, to those sending stamp to pay postage. Persons wishing plants in large or small quantities, may receive them by express, for wet or dry soil. Address GEORGE A. BATES, Bellingham, Norfolk Co., Mass.

HORSE POWERS,

Have taken the HIGHEST PREMIUMS WHEREVER EXHIBITED! NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS last year.

THE MILL may be driven by horse, water, or steam power, does its work equally as well as the best flat stone mills in milling establishments, and requires but one-half the power to do the same amount of work. They are made in the best manner, and will last thirty years, and cost nothing for repairs.

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT. more work than ANY OTHER POWER IN USE.

EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

Liberal discount to dealers—Agents wanted. State, County, and Shop Rights for sale.

THE CRAIG MICROSCOPE.

This is the best and cheapest microscope in the world for general use. It has just received the First Premium—Silver Medal—at the Ohio State Agricultural Fair. It requires no focal adjustment, magnifies about 100 diameters, or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of \$2.25, or with six beautiful mounted objects for Three Dollars. Address

HENRY CRAIG,
182 Centre-st., New-York.

The NONPAREIL WASHING MACHINE

Has been in operation since April, 1861, and the severe and varied tests, to which it has been subjected, in country and city families and laundries, demonstrate that two-thirds the labor and time, and half the soap required in hand washing, are saved by its use, and no injury can possibly result to the most delicate fabric from its action. It is a squeezing machine, and it washes with equal effectiveness a cambric handkerchief, or a bed quilt.

The machine is carefully made of the best materials, and its strength and durability will be found in keeping with its extreme simplicity. There is nothing in its construction liable to get out of order; and no training is required to enable the least skillful person to work it satisfactorily. A girl twelve years old can operate it.

Three sizes of family machines are made, their capacity being about the bulk of five, eight, and twelve shirts respectively. Prices: No. 1, \$12; No. 2, \$16; No. 3, \$20.

Machines to go by Power are manufactured for the use of Hotels and Laundries.

Circulars, giving full descriptions, will be forwarded by OAKLEY & KEATING, 73 South-st., New-York.

See *Agriculturist* Premium No. 3.

Acknowledged to be Superior to all Others.

495 BROADWAY, NEW-YORK.

"Grover & Baker's is the best."—*Am. Agriculturist*.

TEETH UPON ALLEN'S SYSTEM

CAN BE OBTAINED AT

22 Bond-st., New-York.

By this method the TEETH, GUMS, ROOF, and RUGÆ of the MOUTH are all truthfully represented, reflecting those delicate tints, shades, and forms peculiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evinced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, which rejuvenates the waning cheek.

A descriptive pamphlet may be obtained by addressing DRS. J. ALLEN & SON, as above.

These convenient Portfolio Paper Files are for sale at the office of the *American Agriculturist*. They are of various sizes, from the large folio to small octavo.

Those made expressly for the *Agriculturist* are worth 60c., 75c., and \$1, according to quality, to which 23 cents must be added if to be sent by mail.

ALDERNEY BULL AND HEIFER FOR SALE,
A two years old the coming March, both of the best imported stock, at a very moderate price. Apply to JOHN T. CAMPBELL, Jamesburg, Middlesex Co., N. J.

BAUGH'S RAW BONE SUPERPHOSPHATE OF LIME.

BAUGH & SONS,
MANUFACTURERS AND PROPRIETORS,
No. 20 South Delaware Avenue,
PHILADELPHIA.

This Manure is manufactured from pure Raw Bones, and warranted to contain all their original organic matter—no burned or calcined bones are used, and it is sold under a guaranty from the manufacturers that it is free from adulteration.

Last season the demand for this manure exceeded that of any former one, and with few exceptions the results have been highly favorable. No pains will be spared to maintain its standard of popularity. **SEND IN YOUR ORDERS EARLY.**

Price, \$45 per 2,000 lbs., Cash.

TO FARMERS AND OTHERS.

We are manufacturing a Genuine Article of FINE, MEDICUM, and COARSE BONE DUST, or RAW BONE SUPERPHOSPHATE OF LIME, manufactured from unburned Bones, containing all the Animal and Chemical Fertilizing Properties. Please address the Manufacturers, and get the Intrinsic Value of your money.

100,000 BARRELS

OF THE

LODI MANUFACTURING COMPANY'S

POUDRETTE,

FOR SALE BY

JAMES T. FOSTER,

66 COURTLANDT-ST.,

NEW-YORK.

In lots to suit purchasers. This Company have the largest capital and factory of the kind in the world, and possess the best facilities for manufacturing the night soil of New-York City, for which they have the exclusive contract, into a dry, inodorous, but powerful manure—superior to any other fertilizer in market, taking cost and YIELD into consideration. Price \$1.60 per barrel, free from cartage, for any quantity over 7 barrels—or only \$16 per ton.

Beware of spurious imitations, put up in barrels to resemble this Company's brand.

Attention is called to the following letter from a farmer:

FARMINGTON, N. H., OCTOBER 9, 1862.

JAMES R. DEX, ESQ., President Lodi Manufacturing Co.

For several years past I have used as a fertilizer, the Lodi Manufacturing Co.'s Poudrette. I commenced in 1859. I then had a tenant carrying on my farm upon shares. He agreed to use such artificial means as I should furnish free of expense to him, but he had but little faith in anything but barn-yard manure. I purchased some Poudrette. He took it from the freight-house; opened it; came to me with eyes wide open, and said, "YOU HAVE GOT CHEATED. THIS STUFF IS NOTHING BUT DIRT." I told him, "I supposed I had; it was nothing new; I was in the habit of getting cheated, but as it cost him nothing, I wanted him to use it."

We had a piece of poor, sandy loam land, which he planted with potatoes, without manure. He put Poudrette on the hills eight rows, then omitted eight rows, and then put lime in the hill, as he had a mind to try that.

The result was, that where the Poudrette was put, the potatoes came up three or four days before the others. The tops were twice the size during the season, and at harvesting we measured two lots of each, one of which the Poudrette gave twice the quantity of potatoes, and the other in the proportion of five to three.

The lime had no perceptible effect.

We had a piece of corn land, sandy loam, (my tillage land is sandy and gravelly loam,) the corn had a liberal dressing, say ten cords of barn dung to the acre, spread upon grass land, a part ploughed in the fall before, the balance in the spring. The tenant prepared a compost to put in the hill, a mixture of night soil, hog manure and loam well mixed, several times shovelled over, and well incorporated together. This was put in the hill. In eight rows through the middle of the piece, this was omitted and Poudrette was substituted instead. The result was, the Poudrette brought the corn up sooner, of a better color, and at the end of two weeks after it came up, nearly twice as large, and it maintained it a head and shoulder above the other during the season. At harvesting, we measured the corn, and where we got five bushels with the compost, we had six bushels with the Poudrette.

This satisfied me, and convinced my unbelieving tenant that it was something besides dirt. I have used it with whatever I plant ever since, and shall continue to do so, as long as it maintains its character, and is furnished at reasonable prices. We sometimes think we save an entire crop of corn by the use of Poudrette, in case of early frost, as it brings the crop to maturity at least a week earlier.

There has been an increasing demand here since it has been introduced, and from my own observation, and the information of others, I think it does as well on upland soils, as upon sandy loam. I have not been so particular since my first experiment, but every year I left a few rows so as to be sure that it maintains its character. The present year there is a very marked difference in the appearance of a few rows left without the Poudrette, in a piece of corn not yet harvested. The appearance of your Poudrette to one not accustomed to it, is not very flattering. I will relate an anecdote on this point. In 1859 I prevailed upon a neighbor to try a couple of barrels, for which, I think, he paid me \$4.20. He informed me afterwards, that he took it into his field all alone, and opened it; said he, I said to myself, if some one will come along and give me a dollar, he shall have both barrels. No one coming along, he tried it, and has used it every season since, and thinks very highly of its fertilizing qualities. Some of my neighbors have said to me, that they thought it had been worth to them \$5 per barrel. I have used other fertilizers, such as Guano, Superphosphate, &c., most of which are beneficial, but none come fairly up to the Poudrette. One particular advantage Poudrette has over other fertilizers, is that the smell is not offensive, and it will not kill the seed.

And again, it is not so expensive. My method is, to PUT IT IN THE HILL WITH THE SEED. A quart by measure is ample for ten hills, at which rate a barrel will manure a thousand hills. I have known it to do well when a less quantity was used. I think nothing else should be put with it. It is a light matter to put it in the hill with the hand, as a person can drop it better than a boy can drop corn. And it does not require the large hole necessary to put dung or compost, and is a protection against the wire worm.

Respectfully yours,

GEO. L. WHITEHOUSE.

The Company's pamphlet, containing directions for use and other valuable information, will be sent free to any one applying for the same.

A Thousand Thanks

To our readers for their substantial expressions of good will. Subscribers have come in during the past month in far greater numbers than ever before. Owing to the greatly increased cost of printing paper, we expected to lose some thousands of dollars this year, but it now begins to look as if our readers would not allow that. One name more from each present subscriber would put everything all right—and more. Can we have that name this month? Will the reader contribute one name? There is doubtless some neighbor or friend who will be benefited by perusing the *Agriculturist* for a year. It costs

Less Than Two Cents a Week.

The Engravings are worth over Two Cents a Week. The Hints on the Work of the Month shall be worth more than Two Cents a Week.

The thousand or more items given in The Basket shall be worth more than Two Cents a Week.

The chapters on Farming, Animals, Implements, etc., shall be worth more than Two Cents a Week.

The information about the Orchard shall be worth more than Two Cents a Week.

The practical hints for the Kitchen and Flower Gardens shall be worth more than Two Cents a Week.

The Household Department shall be worth more than Two Cents a Week.

The Boys' and Girls' Department shall be worth more than Two Cents a Week.

The whole paper will certainly be worth more than Two Cents a Week.

Please tell all your friends everywhere, and ask them to send in their names. They will be pleased, the publisher will be pleased, the editors will be pleased—we'll all be pleased. Let us have the good time this month.

Good Premiums Still Offered.

We continue the offer of premiums another month. [See remarks in *italics* at head of list on page 60.] We are now sending out many hundreds of these good articles. A little effort will secure, without cost, valuable books, household implements, etc. Lists partly filled can be completed, and new premium clubs can still be commenced. Who will have a premium this month?

Books have advanced (see list page 61) and will advance more if Congress does not take off the duty on paper. Now is the time to secure them as premiums, or otherwise.

Don't Send Money by Express.

Numerous letters containing small sums, are continually being sent by express, on which the expense is ten to twenty per cent. of the whole amount enclosed. It don't pay in these high priced paper times, to send ten copies for \$8, and then to pay from 50 cents to \$1.50 in express charges. Small sums come very safely by mail, if the letters are properly sealed and directed. Larger sums are sent cheaply in the form of a draft on a City Bank, payable to the order of the publisher—not in individual checks on distant Banks, which must be sent for collection at considerable outlay of time and expense.

Can at any time be increased, by remitting for each addition, the price paid by the original members—provided the subscriptions all date back to the same starting point. The back numbers will of course be sent to added names.

About the Seed Distribution.

On page 58 we republish the list of seeds, with some emendations, and a special note to Canada Subscribers. We regret that the Canada postage laws, or rather the method of construing them at some of the Offices, is not more liberal. Of those sent last year with the U. S. postage prepaid here, most went through all right; but in other cases an additional 20 cents an ounce was added at some offices on the way or exacted when delivered. To thousands of our Canada subscribers some of these seeds would be of special value, but 20 cents an ounce is too great a tax.—No seeds will be ready for delivery at the office or by express until March. They are all put up at our country place, and those sent by mail, are mailed there. By our method of putting up, it sometimes happens that of two envelopes sent to the same person, one may be mailed several days before the other, if they contain different kinds of seeds.

Shinplasters at a Discount.

The United States "Postage Currency" is the only kind of small bills that can be used in this city. Small notes issued by other cities, by corporations, and by individuals, can only be sold at a large discount, varying from 10 to 30 per cent, according to their distance from home, and the known character of the corporations issuing them.

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Bound Volumes and Back Numbers can be Supplied.

We have complete sets of Vols. 16, 17, 18, 19, 20, and 21, both unbound, and bound in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, 20, and 21, unbound.....\$1.00 each.
Volumes 16, 17, 18, 19, 20, and 21, bound.....\$1.50 each.

PRICES WHEN SENT POST-PAY BY MAIL.

(They can not go unpaid.)

Volumes 16, 17, 18, 19, 20, and 21, unbound.....\$1.12 each.
Volumes 16, 17, 18, 19, 20, and 21, bound.....\$2.00 each.

BINDING.—Sets of numbers sent to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 12, to 21 inclusive, at 25 cents per cover. Covers can not go by mail.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH, alone worth the cost of the paper.

A full CALENDAR of OPERATIONS every month. THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE,
(For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only six cents a year, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M.,
EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.
Published both in English and German.

(\$1.00 PER ANNUM, IN ADVANCE
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 96.

VOLUME XXII—No. 3.

NEW-YORK, MARCH, 1863.

NEW SERIES—No. 194.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

The Calendar tells us that it is Spring; and though the weather may be less mild than during nearly all of last January, yet the lengthening days, here and there the swelling buds of the early trees, and the appearance of the Liver-leaf in places where the snow has gone, remind the farmer that his time of comparative leisure is nearly over, and he begins to be impatient to commence his season's work. This month of transition from Winter, one which witnesses the contest of the seasons for the mastery, is the occasion of many a skirmish between the rear guard of the retreating forces of the frost king, and the videttes of Spring. Sometimes the advance is so slow, delayed by late snows and lingering cold, that the active farmer chafes at the tardy progress, and is half inclined to fear that seed time may not come according to the promise. An unusually mild Winter throughout the country has saved a great amount of fodder, yet the daily decreasing store is now looked at with solicitude, for it will yet be a long time before the pastures yield food for the beasts, and during many weeks to come the provisions already secured, must be the sole dependence. The crude old couplet "On February, fourteenth day; Half your corn and half your hay," is not far from a true statement.

Notwithstanding the teachings of the journals and the example of thrifty farmers, the agriculture of our country is characterized by a great deal of careless waste. Many farmers have not learned that saving is as important as producing. In almost every neighborhood we find examples of wasteful feeding, where the cattle trample under foot nearly as much as they eat. There are whole districts where almost every other man uses the public highway for a barn-yard.—If the contents of the hay mow and corn crib have so far diminished as to suggest a lack of

feed to take the animals safely through, the manner of feeding should be looked into, to see if it be done in the most saving way. In good feeding there should be just as much put before the animal as it will eat up, and no more. A correspondent writes us that "it is a sin to throw fodder to the cattle in the barn-yard so that they can tramp on it, when feeding boxes like those described on page 12 of the *Agriculturist* for 1862 can be so cheaply made. It is a pleasure to see cattle eat out of them, and nothing is wasted."

But with all our individual faults, agriculture, as a whole, has made great progress, in the manner of cultivating the main crops and economy in using them, and also in the introduction of a diversity of products. The war has brought changes even in the domestic economy of the smallest farms, and individuals as well as the nation are impelled to develop their resources. Besides the staples of wheat, corn, etc., sorghum, flax, cotton, and tobacco are either being successfully cultivated as regular crops, or are the subjects of important experiments. Before the work of the season fairly begins, there is still time to consider whether any change shall be made in the usual routine of crops. The readers of the *Agriculturist* will bear us witness that we have never advised them to go blindly into any new project. We hold that there is a wise medium between that old fogysm which rejects everything and that rashness which adopts everything, and both for the same reason—because it is new. In a country so extended as ours, and with such a diversity of soil and climate, the experience of one locality will not answer as an infallible guide for the whole; hence we are cautious in recommending the general adoption of new things until they have been tried in widely different situations.

With regard to sorghum, we consider that it has ceased to be an experiment. The syrup crop of last year, enormous as it was, will probably be increased during the present year by millions of gallons. The question, in a large portion of the country, is not, will it succeed, but will it pay on the small scale? With proper implements, good and cheap syrup can be made, but the farmer does not feel warranted in procuring these to merely make the sweetening for his own family. There is need of concert of action in the neighborhood. The farmer would plant the cane if he could get it manufactured at a fair rate, and the one having the capital, would willingly invest it in a profitable apparatus, if he were sure that there would be a demand for it. Now is the time to canvass this matter, and see if any arrangement can be made to enable more farmers to grow their own sweetening.

The scarcity of cotton has given a new interest to flax culture. The manufacture of flax-cotton or wool, from which so much was hoped, is yet an experiment, but one which is by no means abandoned. Manufacturers say that they

can work up flax if they can get the raw material, and ask us to advise farmers to plant it. The farmer is ready to grow flax if he can find a demand for his crop, but can not afford to engage in it at a venture. While we can not, without more light on the subject than we now have, advise the general culture for the fiber, we nevertheless counsel farmers to be awake to the subject, and see what facilities their particular region offers for disposing of flax products.

In some parts of the Northern States, cotton can doubtless, at the present prices, be raised at a profit, but we have not seen any results which show that it would be a paying crop at the ordinary price of the staple in peace times.

The growing of tobacco has become an established fact, even in localities where a few years ago it would have been thought impracticable. We have been censured by some, for offering premiums for essays upon the culture of this foul weed. We can not argue the morality of tobacco raising, any more than the growth of apples for cider, grapes for wine, or barley for brewing. But it has been, is, and probably will be, one of the staple crops of the country. While we advise no one to grow it, we can not disregard the demand of a very large number of our readers for information upon the best modes of culture. It is certainly better that they should know the real nature of the crop, than to grow it—as grow it they will—in ignorance of its damaging effects upon the soil. Whoever undertakes the culture, should keep in mind the worn-out tobacco fields of Virginia, and not use up the productive forces of his machine—his farm.

Work for the Farm, Household, etc.

After an unusually mild Winter, we may look for more or less of cold weather this month, in which case the hints for January and February should be borne in mind. The reader will understand that we are not giving rules to be blindly followed, but suggestions to help him "to think of something he did not think of."

Buildings.—The fierce winds of this month will be sure to find every loose piece of siding. See that the animals do not suffer from a cold draft, which the driving of a few nails will stop. Have a contrivance for fastening barn doors open, as well as shut. We have known a barn-door swinging in the wind to inflict serious injury. Look out for loose blinds and shutters; they soon bang themselves in pieces. Painting may be done, though a driving rain is injurious to a coat of paint if it comes upon it before it is dry. If not done early, the hot sun will injure the permanency of the paint. As a rule, autumn is preferable to late spring painting.

Cattle.—See suggestions above, on feeding cattle. After some mouths of dry fodder, cattle long for something green. This craving can be in part satisfied by feeding roots. No animal should fall away in flesh; working cattle should

be well fed and brought gradually into hard work. Cows near calving should have roomy stalls at night. Don't forget to use the card on cattle.

Cellars.—Remove the banking up, and ventilate as soon as danger from cold is past. If cabbages have been kept in the cellar, see that no leaves are left to decay and cause foul odors. Clean out rubbish generally, and apply a coat of whitewash.

Clover.—This may be sown the present month. By taking advantage of a light fall of snow, the clover can be seen and the sowing be done more evenly. The melting snow will carry the seed into the little crevices in the earth. We have had the best success, however, in sowing upon wheat and rye toward the close of freezing weather, choosing a still morning when the surface is well opened by frost cracks. The thawing soil closes over and covers the seed.

Drains.—If the land is not underdrained, surface drains are better than none. Clear out open drains especially in the wheat fields. Commence laying tile or stone drains as soon as the ground will allow working. See notes last month. Obstructions should be removed from those drains already laid.

Fences.—Have material ready to build as soon as the frost is out of the ground. Gates in place of bars are great savers of time and consequently of money. There are plenty of stormy days in which they can be made. Where rail fences are used, the appearance of the whole farm is greatly improved by sawing the ends of the rails square and making them all of equal length.

Grain.—Keep free from injury by dampness, or mice. Consider if you are raising the best sorts. It costs as much to cultivate a poor, as a good variety.

Help.—Hire as soon as possible. As stated last month, better secure a good man a little before he is actually needed, than to wait and take the chances when work presses. Avoid great story tellers, village politicians, and bar-room frequenters. Where there are several men employed, assign to each one his duty so definitely that there will be no shirking. A little personal responsibility for the well doing of a job, often incites a laborer to care and industry.

Hogs.—Keep them at their proper business—making manure. See page 79. Litters of pigs may be looked for. Provide proper bedding for breeding sows. Cooked roots will be relished by them, and will be found nutritious.

Horses.—As their work increases, give more care to their feed. Add carrots to their daily rations, if you have them. Recollect that it is as injurious for a horse to stand in a cold wind after becoming warm from exercise, as it would be for yourself. Do not let the horses forget that there are currycombs.

Ice.—In many localities, this, on account of the mild winter, is yet to be secured. Do not let the first opportunity pass. Better take poor ice than none. If the quantity is small and the quality poor, extra care should be taken for its preservation.

Maple Sugar.—See hints on page 39, of last month.

Manure.—This can be advantageously hauled to the fields while the ground is still frozen. Fork over compost heaps and see that fertilizers from every source are saved. Muck and plaster occasionally thrown into the privies, will prevent unpleasant odors, and furnish valuable poudrette.

Pasture and Grass Lands.—Remove bushes and stones. Read article on regenerating old pasture lands on page 42, last month. Meadows are usually improved by a top-dressing of compost, bone-dust, or ashes. Keep stock of all kinds out of them.

Plowing.—There are few northern localities where plowing can be done in March. This is one of the operations in which it is well to "make haste slowly." It should only be done where the land is in such a condition that it will be left mellow. Have every thing in readiness so that there may be no delay when the proper time arrives.

Potatoes.—In some places early varieties may be planted the last of the month. Secure best sorts.

Poultry.—If they have been properly kept during

the winter, there should be plenty of eggs now. Give cabbages and boiled potatoes for a change from grain, and a supply of chopped refuse meat. Set for early chickens.

Seeds.—Procure the needed stock at once, and not put it off until planting time. Too much care can not be given to secure one of the first essentials of good culture, good seeds.

Sheep.—Some early lambs may be dropped during the latter part of the month, they will need shelter and care. Breeding ewes should be separated from the rest of the flock, and fed with a little grain, and with roots if on hand.

Tools.—Are they all ready? Don't neglect them now and waste valuable time by and by in tinkering and sending to the blacksmith. Recall the old adage of "two strings to your bow," and of all parts particularly liable to break or be lost, such as plow points, etc., have spare ones on hand against accidents. It is cheaper to keep on hand three extra plow points or shares, harrow teeth, whiffle-trees etc., than to lose a half or whole day in the best working season, in going after or making the needed implement.

Orchard and Nursery.

The open season will probably allow of early work in this department. Send orders to the nurseryman as soon as a selection can be made. This is likely to be a busy month in the nursery, and the nurseryman should be prepared with everything that will facilitate his spring's business.

Apple Trees.—Scrape the trunks of old trees, and wash with a strong solution of soft soap or weak lye. Plant early. See if there is not some unoccupied spot that will admit of a tree. The list of varieties determined by the Fruit Growers' meeting, will be too late for this month's paper, but will appear in April. There are certain standard sorts that are good everywhere, and others have been proved by your neighbors. Plant largely of the best market varieties and fewer of the fancy sorts for home use.

Grafting.—This may be done with cherries. Other fruits should be left until next month. Root grafting if not already finished, should be completed and out of the way of other work. If you are so unfortunate as to have an orchard of poor natural fruit, make preparations to graft it with good sorts. If the cutting of cions has been neglected until now, attend to it at once, and keep them in earth or sand until wanted.

Insects.—No trees should be sent from the nursery or planted, that are covered with scale. The moths of some destructive worms ascend the trunks during the present month. Paper smeared with tar mixed with oil enough to keep it soft, and tied around the trees, will arrest a great number.

Manures.—Ground for planting should be prepared with well decomposed manure. The practice of surface manuring fruit trees is growing in favor. The soluble portions are carried down by rains, and the coarse material is left as a mulch.

Pruning should this month be confined to removing dead limbs and cutting out small shoots and suckers. If necessary to make a large wound, cover it with grafting wax or other composition.

Transplanting and Planting Out may be done with deciduous trees and shrubs as soon as the frost is well out of the ground, and it is not wet and heavy. Evergreens should not be moved at present.

Kitchen Garden.

It is very difficult to give directions for the present month, on account of our great diversity of climate, which is perhaps more apparent now than at any other season. In the middle and southern States the weather will doubtless admit of extended operations, while in many northern localities the ground is still closed by frost. Along the seaboard, the influence of the warm breezes is felt in rendering the season much earlier than at some distance inland in the same latitude. Hence, while in many places

the hints here given will be timely, in others those of last month should be noticed, and these reserved for April. The notes upon the small fruits are placed under the separate department of "The Fruit Garden." Where the space is limited, the small fruits may be cultivated with the vegetables; but where there is sufficient land available, it is on many accounts desirable to have a separate place for them. If the work has not been planned, as suggested in January, there is yet time to do it. Read the article on "Rotation in the Garden," on page 51, in February *Agriculturist*.

Artichoke.—This is seldom cultivated in our country, except by Europeans. It is a plant bearing a large thistle-like head, the scales or flower cups of which are eaten. Old beds should be cleared of their winter protection, and a dressing of manure forked in. Make new beds by planting the offsets of old plants, 4 feet apart each way, in deep rich soil.

Asparagus.—The manure placed on the beds last Fall, may be forked in as soon as danger from frosts is over. Apply brine or salt freely. Early cuttings can be readily obtained by forcing. Cover a portion of the bed with a hot-bed frame, bank up around the frame with stable manure, and cover it over with sashes. Lettuce may be sowed between the rows of asparagus. Make new beds, using roots one or two years old, if obtainable. If not, sow seed to produce roots for future use. This is one of the best very early table products of the garden.

Cabbages and Cauliflowers.—Sow in hot-beds for early planting out. The young plants are usually benefitted by ashes and plaster. Allow plenty of air to harden the plants before transplanting.

Cabbage Stumps, set out, to furnish spring greens.

Cold Frames.—These are frames covered with sash, like those for a hot-bed, and are placed on good mellow soil without any heating material. They should be banked up slightly with earth, to prevent the cold winds from creeping in between the frame and the soil. They should be covered with mats or shutters in cold weather. They answer to winter over many half hardy plants. Cabbages and cauliflowers may be sown in Autumn and kept through the winter in this way. Cabbages, lettuce, radishes, etc., may be obtained in them much earlier than when sown in the open ground. When the plants have started, give plenty of air on fine days.

Compost.—The heaps should be turned over, all coarse stones and rubbish picked out, and, if not sufficiently decomposed, some stable manure should be added to induce fermentation. See item on fining manure, on page 73.

Cress or Peppergrass.—Sow early. It is very liable to attacks from insects,—apply ashes freely.

Drains.—If the garden is not already drained, manage to get in a few tiles or covered stone drains in the wettest places. Well drained soil can be worked earlier in Spring, and yields better returns.

Egg Plants.—For early, sow seed from the middle to the last of this month, in a sheltered place.

Fences and Gates.—Put in a condition to repel the depredations of poultry, swine and other animals.

Herbs.—The perennial herbs, like wormwood, mints, hyssop, etc., may be divided and reset.

Hops.—Roots may be planted and poles provided.

Horse-radish.—Dig for family use and for marketing. Though generally left to take care of itself, it is much improved by liberal manuring. New beds may be made by planting crowns or pieces of root.

Hot-Beds.—May be made from the middle to the last of the month. See Calendar for January, for construction of frame and sash. Fresh horse manure is the best material for generating heat. If this is mixed with an equal bulk, more or less, of leaves it will give a more gradual heat, and will last longer. The manure should be thrown into heaps and when fermentation commences, it should be turned over once or twice before making the bed. The bed may be made upon the surface of the ground, or an excavation a foot deep, and a foot wider each way than the frame may be made. The ma-

nure should be laid evenly and packed firmly by striking it with the forks, taking care to fill up the soft spots and have the whole mass uniform. The sides should be laid up square and workman-like, and the fine manure which will be left from the heap, be shoveled up and distributed over the top. The mass of heating material should be at least 2 feet thick. Place on the frame, and put in 5 or 6 inches of rich earth, which should have been in readiness the previous Fall. Cover with the sash, and allow the earth to become well warmed. The temperature should be 60° to 70°. If the earth becomes too hot, open the sash. The seeds may be sown when the earth is of the proper temperature. Shade until they are well up. Guard against excessive heat at mid-day, by lifting or removing the sash, and against cold at night by a protection of mats or other cover. The manure, after hot-beds are done with it, is in good condition for later crops.

Leeks.—Sow in drills 15 inches apart in rich soil.

Lettuce.—Sow in hot-beds or cold frames, and in the open ground as soon as it can be worked.

Manure.—The free use of manure is one secret of successful gardening. Muck, ashes, kitchen slops, scrapings of the barn-yard, hen and pigeon manure, should all be carefully saved.

Mustard for Spring salads: sow in one-foot drills.

Onions.—Potato or multiplier, top onions, and sets, may be planted for early use. Seed should not be sown until the ground becomes warmer.

Peas.—Some of the early kinds may be sown in a warm spot. Plant where any well manured crop stood the year before. The pea-weevil may be killed by pouring scalding water over the peas before planting. It will not destroy germination.

Turnips.—Those which have been left in the ground through the Winter may be dug for use or market. Leave enough of the finest roots for seed.

Peppers may be sown in a hot-bed.

Plow and subsoil whenever the soil will allow.

Potatoes.—Plant for an early crop. The early varieties are numerous, each locality having its favorite sort. Around New-York, the Dykeman is the one most cultivated. The Ash-leaf Kidney is a favorite with many. We have seen a kind at the West, called Early Shaw, which was there considered earlier and better than any other variety. Secure seed in season. Those put in early, should be planted deeper than usual, and it is well to have litter handy to throw over them, if frosts should occur after they are up. Several days may be gained by starting the potatoes before planting. They may be laid in a hot-bed or cold frame, or started in a warm place on bits of sod, which are to be plauted out. In whatever way the potatoes are started, they should have plenty of light, as sickly shoots raised in the dark will usually die off after planting.

Radishes.—Sow in hot-beds. They should have a bed to themselves, and the tops kept as cool as possible. Sow in the open air the last of the month.

Salsify.—Dig for use, leaving enough for seed.

Seeds.—Procure the season's stock if not already done. If you can not rely upon your own experience, consult the list given on page 36 of February *Agriculturist*. See "Germination of Seeds" on another page. Roots which have been kept over to raise seeds from, should be put out early in good soil. Let only the most vigorous shoots grow.

Spinach.—Remove the covering from the Winter beds, and stir the soil between the rows. Sow seed of the round-leaved variety for a Spring crop.

Tools.—Have everything in repair, and purchase improved sorts. Make now, all garden conveniences that will be required, such as markers, stakes, etc.

Tomatoes.—Sow in hot-beds, to be transplanted to another bed, or potted as soon as large enough.

Trench deep, as soon as the ground can be worked.

Turnips.—Sow in a warm spot for early table use.

Winter Cherry.—Sow in hot-beds for early fruiting.

Fruit Garden.

In the directions for the Kitchen Garden above, it is recommended to have a separate department for fruits. This is often impracticable, and it is necessary to grow small fruits among the vegetables. Even in this case, it is better to devote particular divisions to vegetables and fruits, than to mix them indiscriminately. Where a new fruit garden is to be laid out, a place should be chosen which is sheltered from cold winds, and the soil should be deep and well drained. The garden should contain an abundant supply and variety of small fruits, and of dwarf apples and pears, peaches, cherries, plums, etc. Dwarf trees occupy little room, and bear fruit much sooner than standards. Strawberries may be successfully grown between rows of dwarf trees and grapes. In stocking the garden, procure only well established varieties, unless disposed to expend time and money in testing novelties. New things are not always valuable in proportion to the amount of puffing they receive. In buying nursery stock of any kind, procure that which is good and true to name, in preference to that which is low priced. Except in very new countries, there is generally a reliable nurseryman within easy reach, and where there is not, trees and plants can be readily sent to a great distance with the present facilities for transportation. The ground should be prepared early. In no place will thorough manuring and deep working of the soil pay better than in the fruit garden.

Blackberries.—Plant at least 6 feet apart, cutting the canes back to within 6 inches of the root. The New-Rochelle and the Dorchester are still standard varieties. The New-Rochelle grows vigorously, bearing abundant fruit of large size. It is esteemed too sour by many, generally owing to the fact that it is gathered too soon. It blackens some time before fully ripening.

Currants.—Prune, and secure cuttings at once, if not already done as directed last month. Set out rooted plants. The Cherry, Red Dutch, and White Grape, are among the best varieties.

Figs.—These may be cultivated in this latitude, if the trees are laid down every Fall and covered with soil, or surrounded with barrels filled with earth. They should not be uncovered until settled weather.

Fruit Trees.—Plant early and of the best varieties. See article on Dwarf Apples on page 82, and a list of Pears in the January No. on page 17.

Gooseberries.—Prune and make cuttings, and set out new stocks. The "Houghton's Seedling" is productive and succeeds almost any where. The "American Seedling" is highly spoken of, but we have had no experience with it.

Grapes.—It is now too late to prune with safety. Vines which have been laid down for protection should be put up as soon as the weather becomes settled. In localities where late frosts occur, it is better to leave them until next month. Fork a good dressing of manure into the borders. See "What grapes to Plant," on page 83, also page 96.

Raspberries.—If the weather is suitable, uncover buried canes, cut them back to 4 or 5 feet, and tie up to stakes. In making a new plantation, the Franconia, pure Red Antwerp, and Brinkle's Orange will be found to be good varieties. The improved varieties of the BlackCap are very productive. Use manure freely in the soil.

Strawberries.—The covering may be removed as soon as Spring opens. Prepare beds for planting in April and May, using plenty of well decomposed manure. Muck and ashes are good fertilizers.

Trellises.—Put in repair, and erect new. Next month we intend to give a plan for a grape trellis.

Flower Garden and Lawn.

Novices make a great mistake in doing work in the first warm days of Spring, that should be left until settled weather. There is plenty to be done in the grounds, however. Unless unusual care has been taken, there will be remains of last year's vegetation to clear up, broken limbs of trees to be re-

moved, leaves to be raked from the lawn, and picking up generally, to be done.

Annuals.—Those intended for early blooming, may be started in a hot-bed or cold frame or at the last of the month, Asters, Petunias, Balsams, Larkspurs, Phloxes, etc., may be risked in a warm spot.

Bulbs.—The covering of hyacinths, crocuses, etc., may be in part or wholly removed. It is well to have a supply of litter close at hand to throw over them in case it should become very cold.

Cold Frames.—Should have plenty of air to harden the plants before planting out.

Edgings.—Box edgings require resetting as soon as they become shabby. The earlier it is done, the better. Grass edgings should be trimmed with the edging knife, and replaced where the grass is dead.

Gravel.—Old walks should be repaired and new ones made. A layer of stones beneath the gravel acts as drainage and secures dry walks.

Hedges.—Buckthorn, Privet or other deciduous hedge plants may be set this month.

Honeysuckles and other Climbers.—Prune and arrange. Plant out where needed.

Hot-Beds will be needed for early annuals and cuttings. See Kitchen Garden for this and last month.

Lawn.—Dead leaves should be raked up and a top-dressing of compost or plaster given. Sow seed on, or turf over bare spots.

Manure.—This will be wanted everywhere. There should be a large stock of well decomposed compost ready for use.

Perennials.—Dicentra, Perennial Phloxes, Larkspurs, herbaceous Spiraeas, Hollyhocks, etc., should be divided and reset to increase the stock and produce finer bloom than is given by overgrown clumps.

Roses.—Plant and set as early as the ground will admit. Trim and arrange pillar and climbing roses.

Shrubs.—Do not uncover those protected during Winter, until the weather becomes settled. Plant hardy kinds as soon as the ground is suitable.

Green-Houses.

The warmth of the sun will allow fire heat to be nearly dispensed with. Sudden changes of temperature should be guarded against. Plants should be hardened off by free admission of air on mild days.

Bedding Plants.—A good stock of Verbenas, Cupheas, Petunias, Pansies, and the like should be hardened off and ready for outdoor planting.

Cleanliness should be scrupulously observed. Decaying leaves, weeds and moss ought not to be allowed to accumulate upon the pots. Syringe the foliage to remove dust.

Insects will now be on the increase, and especial care will be needed to keep them in check. Fumigation, soap-suds, etc., should be freely employed.

Lemons, Oranges and Oleanders are very apt to be affected with scale. Cleanse with soap-suds applied with a stiff brush. Repot and trim as needed.

Roses.—Those rooted for out-door blooming will need changing to larger pots.

Water.—The quantity should be increased as the plants push more vigorously. Its temperature should be as near as possible that of the house.

Hot House and Conservatory.

The changeable weather of this month will render it necessary to guard against sudden cold. The temperature must be regulated according to the nature of the collections. Neatness should be a characteristic of every well kept house. Shabby plants and those out of bloom should be kept in the back ground, and dead leaves, trimmings, etc., removed.

Abutilons.—These should be propagated for planting out. They make a fine appearance in the ground. *Abutilon striatum* and *venosum* grow from cuttings with the greatest ease; while the *insignis* needs to be grafted on the free growing sorts.

Acacias.—Should now show a fine bloom. Give them little water, and a good exposure to light.

Annuals.—Pot off those sown last month, and sow anew if a larger stock is to be provided for.

Azaleas are now nearly out of flower. As soon as they have done blooming, cut back straggling branches to preserve a neat and compact form.

Bedding Plants.—Cuttings may still be put in, and those already rooted should be potted off and transferred to the green-house or cold frame to harden.

Camellias are still among the attractions of the conservatory. The leaves should be carefully washed without wetting the flowers, which would spoil them. Trenching may be done this month.

Chrysanthemums may be propagated by cuttings.

Calceolarias will need shifting if pot-bound, and fumigating if attacked by green-fly. Water freely.

Fuchsias should now be brought forward. Train to a compact round or pyramidal form, according to the habit of the plant. Repot young plants.

Heaths will need to be shifted into larger pots.

Insects.—These are the gardeners' constant enemies and need his constant care and watchfulness.

Lantanas should be repotted, to flower early.

Pelargoniums should be brought near the glass as they come into bloom, frequently turning them.

Parlor Plants.—There are but few which do well in the dry air of our rooms. The dust should be removed by syringing, or careful washing, and the pots should be frequently turned toward the light, to keep the plants from becoming one-sided.

Syringe the foliage frequently, and keep up a moist atmosphere by sprinkling the walls and floors.

Water should be given freely to growing plants, provided there is perfect drainage at the bottom.

Apiary in March.

After their long winter confinement, the bees will be in haste to improve the first return of mild weather. In some sections considerable pollen will be gathered this month, and in good stocks breeding will go on quite rapidly.... Where colonies have been kept in the cellar, or removed from their usual summer stand, let them be returned in time to commence operations early. It is best to bring them out a few hives at a time, if the number be large. Place them as far apart as practicable, and afterward fill the intervening spaces. This will enable the bees more readily to mark their own location, and prevent loss from their entering the wrong hives. A stranger bee usually finds little mercy in his neighbor's domicile.... Ascertain the condition of each stock on some cool morning as soon as possible after removing. Contract the entrance of the weak ones, until only a single bee can pass at once. Watch for robbing bees on the first warm days—it requires close observation to detect them at first. Ascertain which are destitute of stores, and feed as they require it, taking care not to expose any honey where other bees may get to it. The utility of flour as a substitute for pollen is pretty well established. It is difficult, sometimes, to get them to take it, especially when offered after a little is obtained from the flowers; but when given early, and a taste for it acquired, they will use large quantities. To feed the flour, make a floor several feet square, the size proportioned to the number of stocks. Put it in some warm place within a few rods of the apiary. The unbolted wheat flour is best, but any kind of flour will probably do; buckwheat has been used extensively. Begin by scattering some on the ground or in the grass near the floor; they will usually find it in a few hours. Keep them busy by feeding every fair day. Weak stocks should be fed with honey, or sugar water. Any stock having lost its queen during Winter, will be likely to show it near evening of the first day they fly out freely, by running about in apparent confusion. A queenless colony now should be united with some feeble stock, unless the queenless one is much superior in numbers, and in other respects will make the best stock; in which case, that should receive the bees from the other. The combs

and honey of a queenless hive, if all right, may be set away for a new swarm, taking care to smoke with brimstone once or twice to destroy the worms as they hatch out. If the colony that contains the queen is the one removed, there will be some brood in the combs, necessary to be taken out before putting the hive away. Be careful and not save for a new swarm any combs containing foul brood.

Containing a great variety of Items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

The Basket Full.—We have on hand, in type, and in preparation, for this department, many items which are necessarily crowded over to next number.

Unanswered Letters.—Our readers must excuse us for not promptly answering many letters received, some of them asking "an answer by the first mail." We waste no time, work hard all day, and to a late hour at night, but still find it impossible to answer all the letters marked "for immediate reply." Our readers give us too much credit in supposing that we can write an off hand correct answer to a thousand and one queries about the best treatment of crops, and of soils we have never seen, about the quality of nearly every implement manufactured, etc., etc. The letter-writing season will slacken as Spring work comes on, and we hope to then be able to respond to most of the communications on hand.

A Grape Vine For Everybody.—There is scarcely a family among our readers, whose garden-plot or house-yard might not well contain one or more good grape vines. A few minutes time in preparing the ground and planting, and a little care afterward in training, will soon enable one not only to "sit under his own vine," but to enjoy a supply of delicious fruit. It does not take long for a vine to grow large enough to produce fifty to a hundred pounds of grapes. The Publisher's offer, on page 96, will place it in the power of almost every one to get a vine or two of the best sort, delivered free. Every one will know of two or more friends and neighbors who ought to take the *Agriculturist*, and who would be induced to do so by a little persuasion, or setting forth of its merits. The vine or vines received, can soon be multiplied by cuttings and layers to supply the new subscribers with vines also. We have provided the vines for this special purpose, and hope the additional subscriptions received in this way, will materially aid in meeting the greatly increased expenses of this year, while we believe the distribution of the vines and the circulation of more papers will, at the same time, be beneficial to the country. We trust our friends will be incited by these triple considerations to assist in making this special premium a very successful one.

The General Premiums still Continued.—Those interested in securing any of the good articles in our premium list, will find by referring to page 89, that the offers are still continued. Partial lists can therefore yet be completed, and new premium clubs made up. All names received from any person for this year, can be counted in making up a club for these general premiums. Names for the special grape premium can not be counted in any other list, and this premium applies only to names sent after March 1st. This restriction is absolutely necessary the present year.

The Seed Distribution by mail is in progress. The applications already in will be got through with before the close of March. Seeds to be called for at the Office, will come in from our country place, about the second week in March. As before stated, owing to the increased expenses this year, and no advance in subscription prices, we cannot be as liberal in furnishing seeds free, as we have been hitherto, and hope to be hereafter. New subscribers coming in will be able to still get some of the seeds. Applicants should now send six or eight numbers, and we will select and forward three or four kinds, taking the first on the list sent, that we chance to have. See last month's *Agriculturist* (p. 58.)

The Advertisements Good Reading.—Our business columns are well filled this month, notwithstanding the severe sifting given. Large numbers have been rejected—those from known parties not in good repute, and all from unknown parties not presenting some evidence of their integrity and good repute at home. All humbugs, patent medicines, &c. are of

course excluded. Of all the numerous parties advertising, we think there are none who do not intend to do what they propose to do. The advertisements are arranged mainly to suit the convenience of the printer in making up the paper, and not to give any preference of place to any one. It will be well to look through the whole, and see what is offered, and send for the circulars and catalogues. (It may interest the advertisers to tell them their business notices were seen in the *Agriculturist*, as many of them would like to know in what journal they reach the largest circle of reading, enterprising men.) Some of those who have recently asked for the best way of investing a few hundred dollars now, may perhaps do worse than to put the money into fruit-trees that will ere long pay back a large interest, as well as into good implements, seeds, etc., that will bring immediate returns.

Books Advancing.—As the old stock of books decreases, and new ones have to be made from paper at double cost, publishers are advancing their rates, though they have not nearly doubled them as yet. From present appearances, prices will go still higher, and it will probably be economy to purchase now, any that will be wanted this year. It will be seen by our list on page 91, that we have necessarily advanced the price of several books to the rates now charged to us by the publishers. Those choosing book premiums will, of course, be guided by prices given this month, and not by any previous list.

Pray Don't Send Seed Envelopes to Albia, Iowa!—The directions were full and explicit, yet the Postmaster at Albia (whose office chanced to be taken merely as a model) writes us that many envelopes for seed are being sent to him, instead of to us.

To Correspondents.—It is a growing custom, and one which we do not admire, to make several copies of a communication and send them to the different agricultural journals. It is but fair, when this is done, to indicate to each that it has been sent to other papers.

Write Briefly.—We again repeat that we cannot publish long dissertations. We are always grateful for facts and records of practical experience, but a page of real information is not improved by a preface of two pages of general remarks, and then a long ending.

Postage Only Six Cents a Year.—Complaints still come of over-charges. Will Postmasters please turn to Section 117 of the "Regulations" furnished to them by the Department for their guidance? It is there plainly stated, that the *Quarterly* postage on Periodicals weighing 3 ounces and under, sent to any part of the United States, is on *monthly* issues only 1½ cents, N. B.—This is 1½ cents per quarter, not per number. We only pay paper-makers for 2½ ounces in each number; they certainly would not furnish over "3 ounces" except in a chance thick sheet, made in starting the mills.

Strawberry and Other Exhibitions.—We briefly announce now, that there will be several Exhibitions at the office of the *American Agriculturist*, the present year, with prizes offered, similar to those held last season; say one of Strawberries in June, and probably one of Pumpkins, Squashes and Gourds in Autumn, and perhaps exhibitions of Roses and other Flowers, of apples, pears, grapes, etc., and of several kinds of vegetables. We have been too busy to arrange the matter, and merely make this announcement now, that growers may be thinking over the matter, and offer any suggestions they have to make. Further particulars next month.

Back Volumes and Numbers.—To many inquirers.—Any full volume of the *Agriculturist* from XVI to XXI, can be supplied in numbers at \$1.00 (or \$1.12 by mail.)—If bound \$1.50, (or \$2.00 if by mail.)—Any single numbers from 1857 to the present time will be sent post-paid for 10 cents each. (No German copies on hand, prior to July 1858.)—Numbers lost by Mail supplied free.

"I Don't Get the Paper."—"A week ago I sent you my subscription for 1863, but I don't get the paper."—The above is an exact copy of a letter from Western Illinois, dated Feb. 10. On examination, we found the subscription letter dated Feb. 3, mailed according to the post-mark on Feb. 5; it reached us Feb. 10; was that day placed on the entry-book; and on Feb. 11 the wrapper was written, and the January and February numbers mailed on the evening of the same day. If they went as fast as the letter came, they would reach the subscriber on Feb. 16, six days after his second letter, though papers generally go slower than letters, often much slower. Such is one case, and we have had many similar ones. There are always difficulties occurring, notwithstanding the utmost care and promptness on our part. Sometimes, but not often, the first papers sent fail

to reach subscribers, through carelessness in the mails. Very often a subscriber writes: "Send my paper the same as last year," without telling *where*. Probably one out of ten of all the letters in the country, no matter by whom written or where sent, are simply dated at the P. O., the State being omitted. Our clerks have spent hundreds of hours in studying out the postmaster's stamp, or as that is very often illegible, in looking over the mail-books to find which State a letter came from. If from an old subscriber, this is found; if not, not; and then comes a scolding letter, ten chances to one with the State again omitted, from the general habit of omitting it. We have on file several letters containing money, on which there is not the slightest indication, inside or out, as to where they came from, or who sent them. Such are some of the difficulties we, in common with other publishers, labor under, and we only speak of them in excuse for apparent neglect and want of promptness. It is hardly to be expected that some mistakes will not occur on the part of the *writers* of so many letters. On an average, we have received a subscriber every forty-seven seconds of working-time (10 hours a day) since last November. These names, with the Post-Office address of each, have been picked out of the letters, placed on the entry-books, and transferred to the alphabetical mail-books, and so far not twenty errors have been made when the name and address are fully and correctly sent.

Horn Ail in Cattle.—Albert D. Rust, Montcalm Co., Mich. Horn Ail, or "hollow horn," as it is sometimes called, is a symptom or accompaniment of disease, and not a distinct malady. It often results from severe catarrh. Any disease that greatly disturbs the circulation of blood will produce coldness at the extremities, and severe inflammation about the head would be likely to affect the inner structure of the horns. Remedies should be applied to the seat of the disease. Boring the horns is condemned by our best veterinary authorities.

Hatching Chickens.—S. D. Ingraham, Brown Co., O. Bement's American Poulterer's Companion gives an account of the various contrivances for hatching by artificial means. We are not aware that machine hatching has been successfully done on a large scale. The great difficulty seems to be to raise the chickens after they are hatched. They flourish best when they have the care and protection of the mother hen.

Tobacco in Maine.—H. N. K. writes to know if Havana Tobacco will come to maturity in Maine. We do not know. Probably it will in favorable locations, if started early. Some one else can perhaps answer more definitely.

The Chick Pea.—"Querist," Worcester Co., Mass. We do not know where Wood gets his authority for stating that the Chick Pea is poisonous. It has been used as a food in the old countries for centuries, and we have frequently eaten it in Mexico, where it is an article of consumption, and never heard of its being hurtful. We do not know the "Indicator" you refer to.

Chinese Yam, (*Dioscorea batatas*).—Abner Smith, Pottawatomie Co., Kansas. It is hardly worth while to give the chapter you ask on the cultivation of this plant, as it has been generally abandoned, and never had many claims upon public attention, except in the statements of those speculating in the roots. Planted on very deeply-worked, rich soil, it sometimes does well, but as a rule it seldom pays the expenses of digging.

Sweet Potatoes in Iowa.—Dr. J. W. Smith, of Floyd Co., Iowa—about 43 degrees of latitude—raised three bushels of Sweet Potatoes last year, and with only ordinary cultivation. He obtained the plants May 31, and dug the crop early in October. Some of the potatoes were as large and fine as any grown in the country. The soil was a sandy, prairie loam, resting upon a sand subsoil.

Bitter Pumpkins.—Joseph Philbrick, Bloomfield, Me., writes us that he has raised a hybrid between the common pumpkin and a small "fancy gourd," which had an intensely bitter taste. Those who raise ornamental gourds should not grow them where there is danger of their mingling with squashes or pumpkins.

Covering Strawberries.—Wm. R. Morgan, Harford Co., Md. The largest grower of Strawberries to our knowledge, covers his vines with straw, threshed with a flail. In the Spring the straw is parted so as to uncover the plant, and left on the ground as a mulch, and to keep the fruit clean.

Tan for Hotbeds.—"Querist," Worcester Co., Mass. This as it comes from the tannery is too wet

for use; it should be moist, but not wet. After it has dried sufficiently it is thrown into a heap to ferment, occasionally shoveling it over to admit air. It takes a month, more or less, to bring it into heat. Mixed with manure it heats sooner, and is more lasting than manure alone. Hemlock bark is considered about one-third less valuable than oak bark.

Currants—Best Kinds.—J. B. Welch, Winona Co., Minn. The old Red Dutch, White Provence, La Versailles, and Cherry, are among the best sorts.

List of 1,600 Dwarf Pears.—Geo. R. Underhill, of Queens County, N. Y., (near Oyster Bay.) submitted to us a list of 1,600 Fall and Winter Dwarf Pears, which he prepared to plant for market purposes. We laid the selection before the Fruit-Growers' Meeting, and there was a general concurrence in the opinion that it was a judicious one, excepting that it is not necessary to double-work the Flemish Beauty. The list is: "100 Flemish Beauty (double-worked); 100 Louise Bonne de Jersey; 100 Beurre Bosc, (double-worked); 400 Duchesse d'Angouleme; 200 Beurre d'Anjou; 150 Beurre Diel; 50 Urbaniste; 50 Beurre Superfin; 100 Beurre Clairgeau (double worked); 200 Vicar of Winkfield; 50 Beurre Gris d'Hiver Nouveau; 50 Doyenne d'Alencon; 50 Beurre Langellier.

Balsam Poplar.—Wm. McJunkin, of Alleghany Co., Pa., sends us the pods, and asks us what is the cause of the cotton upon them, and why it had not appeared previous to 1862. The cottony hairs are a natural attachment to the seed, and aid in their distribution by the winds. They were not seen in other years because the trees for some reason failed to perfect their fruit.

Basket for Picking Fruit.—Sometime since we received from Messrs. Monroe Brothers, Fitchburg, Mass., a specimen of a basket which is quite convenient for gathering, or rather for emptying fruit, without bruising. The top is round, but the bottom is carried down square, and is closed by two thin boards. These are hung on hinges at the four corners, so as to close the bottom, or drop down and leave it open. When closed they are kept so by a double wire which passes up through the centre of the basket, and is held to the middle of the handle by a catch. When the basket is filled it is let down into a barrel, or other receptacle, and by slipping the catch the bottom boards drop down and discharge the fruit without the bruising incident to pouring out, or the labor of transferring fruit with the hands.

Fitting Sap-Spouts.—D. Coon, Waushara Co., Wis., writes to the *American Agriculturist* that Sap-Spouts can be very readily fitted for insertion, by using a hollow auger, such as wagon-makers have for boring tenons on the ends of wheel-spokes. He makes the tenon on the spout half an inch long, with a square shoulder to fit against the tree, which prevents leakage. Before tapping, the rough outside bark is shaved from the trunk. The remaining bark is about one-fourth of an inch thick, so that the spout enters the wood only about a quarter of an inch. This gives almost the whole surface of the cut for the sap to escape from.

Water in Lead-Pipes.—A. E. Groff, Owings Mills, Md. We cannot say whether it would be safe to conduct the water through lead pipes without knowing its quality. Very pure water readily acts upon lead. But very little spring, or river water even, is so pure that it may not be safely conducted through lead. Cement pipes are perfectly safe.

A Mild Winter in Indiana.—E. W. Weir, of Lagrange, Ind., sent us specimens of violets and pansies in bloom in the open air, on January 26th.

Home-made Linen.—"M. A. H.," Marshall Co., Iowa, counsels the ladies to leave the piano for the spinning wheel and the loom, to manufacture linen to take the place of cotton for home consumption. This may be advisable in some remote sections, but manufactories already established will do the work better and cheaper, provided farmers will keep them supplied with the raw material. There is usually work enough for the females of every household, without adding spinning and weaving to their labors.

The Address of Soldiers.—Mrs. H. H. D., Windsor Co., Vt. The various regiments of our armies are so constantly changing their location that no one outside the War Department can give the precise position at any time. The best way to address a friend in the army, whose place is not known, is to put upon the letter his name, company, and No. and State of the regiment, and address it to "WASHINGTON, D. C., or else-

where." It will then go to Washington, and be there put into the regimental box, to be forwarded.

Yankee.—S. B. Walton, Harford Co., Md. This word is said to be derived from the attempts of the Indians to speak the word English, which they called Yenghees and Yanglees.

The Short Horn Herd Book.—The Editor of this work (Hon. L. F. Allen, of Black Rock, Erie Co., N. Y.,) writes February 9th: "Your notice of the Herd Book, on page 37, of February *Agriculturist*, partially misapprehends my intention as to publishing 6th Volume Herd Book. It will be published, as usual, if pedigrees enough come in to warrant it, of which I have little doubt, judging from the numbers that I daily receive for record. No time should be lost in forwarding them, that I may proceed with their compilation. I shall probably hold open the work long enough to embrace the Spring increase, provided they be seasonably sent to me. There never was a better time for our cattle breeders to improve and increase their Short Horn herds than now. The demand for them must soon revive, and those who have choice and sufficient stock will reap the advantage."

Practical Notes on Onion Culture.—Several new subscribers inquire "what is the pamphlet on Onion Culture referred to in our columns?" Some time since we offered a premium for the best practical treatise on onion culture, to embrace all items from furnishing seed to marketing the crop, to be written by experienced growers. A large number of good articles were sent in, and after the awarding of the prize by the Committee, we selected seventeen of the best, and printed them in a book or pamphlet of 32 pages. This contains the plain, practical directions of seventeen cultivators, residing in different parts of the country, and is undoubtedly the best source of information to be found on this topic. It is sold, or sent post-paid for 21 cents, (or seven 3-cent stamps—or two 10 cent currency notes will answer.)

"The Employment of Women."—This is a subject of great importance just now. A million men are in the army, and what shall be done by their wives, widows, daughters, and female friends who have hitherto depended upon them? We are glad to announce a really valuable book on this very topic, prepared by Miss Virginia Penny, who has devoted several years to a careful and laborious investigation of the question, and has collected a vast amount of really useful information, which is condensed into a volume of 500 pages. It is a sensible book; is not filled with a diatribe upon woman's rights and woman's wrongs, but goes right to the point, and shows what women are doing, and indicates the branches of labor and business where they are not now employed, but in which they might take the place of men, in part at least. Instead of being called a Cyclopædia of Woman's work, it might be entitled one of human industry, for there is scarcely an occupation upon which it does not contain some interesting information. The different employments, the terms of apprenticeship and rate of wages are given, as well as the relative demand and supply of each kind of labor. We pleasantly passed some hours in turning over its pages, and wonder at the industry which collected such a mass of information, and admire its plain and unassuming style. We believe that the author has done a good work in presenting this book to the public. We esteem the book so valuable that we have placed it in our list of books for premiums, and on sale at the office. Price \$1 50. (including postage, when sent by mail.)

"Wool Grower."—J. S. Johnston, Lawrence Co., Pa. A paper with the above heading was published for some time and then discontinued. Recently it has been revived.

"A Million Postage Stamps."—"G. W. K.," Penn. The collection of a great number of different kinds of P. O. stamps, one of each, has been undertaken by several persons as a matter of curiosity; but the collections of a million referred to in your letter, and in three other reported cases, are no doubt for bad purposes. The parties buying them select the best and wash off the ink carefully, so as to use them again. If they save and use only one out of every ten 3-cent stamps, they make three thousand dollars, and can well afford to give \$200 to some Sunday school or other benevolent object as a blind. All such persons should be promptly reported to the Post Master General at Washington.

Erysipelas.—"M. A. G." writes that a strong infusion of Indian Tobacco (*Lobelia inflata*) in vinegar, applied to the part affected, will allay the intense burning which accompanies this disease. Erysipelas is too formidable a disease to be treated in domestic practice, and we give the suggestion without recommending it.

Is Old Seed Wheat Best?—Daniel J. Banta, Dubois Co., Ind., writes to the *Agriculturist*, that he has been experimenting upon the wheat crop, and among other things finds that seed one year old brings the best crops. It is said, by pretty good authority, that cucumber seeds several years old will produce less vines and more fruit, but this is the first similar statement we have seen with respect to wheat. A considerable number of observations in different localities and under a variety of circumstances, will be needed to settle the question. Who have any facts to put on record?

Wheat Insects.—E. D. Hewit, Columbia Co., Wis. We can not tell what the insects are without seeing them. They can be sent by mail in a box.

Lister's Superphosphate.—Solomon S. Mead, of Fairfield Co., Conn., sends a lengthy account of experiments with manures, which we have not room for. The gist of the matter is, that in all his trials the superphosphate made by Lister Brothers, and ground bones from the same source, have given excellent results. In comparative plots of corn in the same field with equal quantities of this superphosphate, and "Flemish Manure," the superphosphate gave the best results by at least 25 per cent. As this superphosphate is honestly made, we believe, and is made nearly or wholly of unburned bones, simply dissolved in sulphuric acid, we should look for good results from its use. We applied it pretty freely to a plot of oats last year, but were not at home to watch the effect. The man in charge complained that, it was "too good," causing the straw to grow so large as to fall down.

Specimens of Grass.—Andrew S. Nash, a young farmer of Westport, Conn., has brought us a collection of the grasses of his vicinity. We are always glad to see young people, especially young farmers, take an interest in the common plants and objects about them. They will find that there is enough to study without traveling far for material.

When to Sow Millet.—Robert F. Roberts, Racine Co., Wis. Hungarian and other millet may be sowed in Spring at about the time for planting corn, and up to June 10th or later, if for fodder. The Mammoth variety promises to be the most prolific. It is on our list for free distribution in small parcels as a beginning.

Paper from Straw.—Coarse paper has long been made from straw, but the process is now so perfected as to produce a white and strong article. Some of the daily papers in this city are printed on straw paper, and we have been shown samples of excellent writing paper from the same material made by Mr. L. W. Wright.

Corn for Fuel.—The Nebraska Farmer says that corn is extensively used for fuel in some parts of that State. Two bushels of corn are considered worth one bushel of coal, and with corn at 10c. and coal 20c. per bushel, farmers think they may as well use the grain as the mineral fuel. The economy of burning corn was discussed at length in February *Agriculturist* last year.

Cotton Samples.—We have received by mail, samples from Charles Peters, Athens Co., Ohio, and O. P. Williams, of Portage, Wis. The latter thinks that it should be grown as an ornamental plant even where it will not ripen. We have distributed seeds for ornamental purposes several years, and keep it on our list.

Cotton in Utah.—E. H. Howard sends us from Great Salt Lake City, a sample of the cotton grown in Utah. The quality is not quite equal to that we have seen from Illinois. About 200 acres, in Washington Co., were in cultivation during the past season, and gave an average yield of 375 pounds to the acre.

New Cotton Substitute.—Small samples of fiber and cloth made from "China Grass," have been placed on our Exhibition Tables by Messrs. Wright & Whitman, of Boston. The fiber has a very silky appearance, and takes color well. There is also a specimen of the raw material which, though it is called grass, is the product of one of the nettle family, *Boehmeria nivea*. We are not aware that it has been introduced into this country. It is largely cultivated in India, and has been raised in the Royal Gardens at Kew, near London.

Three Crops of Peas in a Season.—E. L. Watts, Lasalle Co., Ill., writes that he sowed the Daniel O'Rourke pea, obtained from the *Agriculturist* distribution, April 10th, and had them in bloom by the 15th of May. Some of the ripened peas were scattered on the ground and produced a second crop, and from the seed of these he had green peas by the middle of September, some of which ripened, making the third crop.

Chicory.—Solon Robinson, Esq., has placed upon our Exhibition Table fresh roots of chicory, and the same article sliced and dried ready for roasting. It is largely used as a substitute for, or to mix with, coffee, but for reasons often given, we can not commend its use.

Hubbard Squash.—S. M. Bell, Rush Co., Ind. It will not do to plant this among corn. If you wish a crop, it must have the ground all to itself, and the soil must be well manured. It is one of the very best sorts.

Squash Worms.—Mrs. C. C. McGinnis, Clinton Co., Ill. Your Hubbard Squash vines were destroyed by the squash bug (*Coreus tristis*). Plant the seeds in well manured soil to insure a vigorous early growth. Look them over in the cool of the morning to find the bugs, which at that time are very quiet. A little vigilance exercised in time will free you from their ravages.

A Paying Crop of Onions.—Hanson Ordway, of West Newbury, raised half an acre of onions which yielded at the rate of over nine hundred bushels to the acre. Corn land was manured the year before with ten and-a-half cords of barn yard manure, which was plowed in 5 inches deep. In the Spring it was treated with 100 bushels of leached ashes, cultivated and harrowed, and raked. The crop, which took a premium from the Essex Agricultural Society, cost \$60.50, and sold (at 1 cent per lb.), for \$251.40,—a handsome margin of \$170.90.

Salt Around Fruit Trees.—M. Foster, Jr., Essex Co., Mass. Two quarts of salt can be safely spread around a pear tree, and frequently with good effect. Let it extend to a distance of ten feet from the trunk. For small trees a less amount is sufficient.

Books on Evergreens.—B. Albertson, Bucks Co., Pa. We know nothing of the work by Brown, to which you allude. The last edition of Downing's Landscape Gardening is out of print. Warder's Hedges and Evergreens contains brief descriptions of the latter. It is in our list of books; see advertisement.

Kitchen Garden in an Orchard.—W. Hendry, Conestoga, U. C. Vegetables may well occupy the ground between rows of young trees; but when the roots extend and need the ground, let them have it; good fruit will pay as well or better than vegetables.

Peach Borer Remedy.—M. Kelly, Fayette Co., Ind., advises to remove the soil for two inches in depth, about the trunks of peach trees, thus exposing the track of the worms. With a sharp knife, or pointed instrument, follow the worm path, which usually goes around the tree, and kill every borer. By attending to this in Spring and Fall, nearly all the trees can be saved. An expert hand can worm 50 or more trees in a day. Of course the earth should be returned about the trees.

Worms at the Roots.—Mrs. Jas. P. Bogardus, Sullivan Co., N. Y., and Mrs. C. C. McGinnis, Clinton Co., Ill. These pests are the larvæ of small flies, and are often so numerous as to quite destroy certain crops in the garden. The only remedy is to repot the plants with soil from another locality. By turning the ball of earth out of the pots and placing it in a pail of water, the soil may be washed out without much injury to the small roots. See that the roots are entirely free from the worms and repot with fresh earth.

Osage Orange Seed.—Wm. Polly, Dark Co., Ohio. In Texas, the source which formerly supplied the most of the seed, it is cleaned by allowing the balls to rot and then washing out the seed.

Grapes for Australia.—James Gamage, Fairfield Co., Conn. It is impossible to tell what grapes will succeed best in Australia. We should advise taking but a small stock of Catawba, Delaware, Concord, and Creveling. Probably you will find some good wine grapes under cultivation there, better adapted to the country than any you can take out with you.

Pruning Grape Vines.—J. Sutton, Bonaparte, Iowa. You did quite right with regard to your vines. In pruning always cut to a bud. Although a branch may come where there is no visible bud, it is not safe to trust to its doing so.

Cranberries.—Wm. Kramer, Dayton, Ohio. We have no facts concerning the culture of the cranberry on dry land, away from the sea-shore. Its success even there is not well established.—"Sucker." Your slough would no doubt make a good cranberry patch if

you have the means of flowing the land during a part of the year—an essential to the successful culture of this fruit.

Treatment of Flowering Shrubs.—Lulu S. Lauber, Lancaster Co., Pa. Unless it is desirable to obtain seed, the flower clusters should be removed as soon as their beauty is past, or much of the energy of the plant will be expended in maturing useless seed.

Chrysanthemum on a Rosebush.—Mrs. James, Harrisonville, Me. We can not undertake to account for an alleged phenomenon without seeing it. While it no doubt appeared that a rosebush bore a chrysanthemum flower, we have no doubt that there is a mistake somewhere. If a like phenomenon should occur another season, please let us see it by all means.

Bridal Rose.—M. S. Shaler, Broom Co., Wis. Your "rose," really a kind of double blackberry, probably needs repotting. Prune severely and repot in rich earth.

Flower Seeds.—S. M. Bell, Rush Co., Ind. We can not tell why your seeds did not come up, without knowing how they were planted. The most common causes of failure are sowing too deeply and sowing too early, before the ground becomes warm enough to make them germinate, when they may rot or lose their vitality.

Things in Center Co., Pa.—A "Subscriber of the *Agriculturist*," writing from this County just at mid-winter (Jan. 14) says: "A most remarkable Winter we are having; no cold weather, hence no ice for ice-houses or skating; very little snow, hence no sleighing; no rain, hence almost no water in our wells and springs; it has not been so dry for many years. Our last wheat crop was good; our corn rather poor; our oats destroyed in some places by army worm; our potato crop below the average, but not rotting; our fruit pretty good; our Union men patriotic; our Secessionists rabid; our volunteers more than the quota; our ladies agreeable and pretty (we think)."

Bees in a Chimney.—L. W. Leake, New-York. In the case of bees making a permanent residence in a chimney, Mr. Quinby says there seems to be no other way but to remove enough bricks near their locality to reach them, quiet them with tobacco smoke, and remove the combs. If it be desired to save the bees, place the brood combs with the bees on them, as near as possible in a natural position, in a hive bottom up, where the bees will soon fasten them; then turn the hive over. The proper season for this would be, after flowers have appeared in Spring, that the bees may repair all damages and continue labor in their new home.

Grain Aphis in 1862.—W. Hendry, Conestoga, U. C. The grain aphis appeared in the same localities in 1862 as during the previous year, and also was found over a much larger extent of country.

Cut Worms.—"G. A.," Harrison Co., Ohio, writes that he has seen the cut worm turn into Hessian Fly. We have no doubt that he has seen some kind of a fly produced from the chrysalis of some kind of a worm. What is generally known as the cut worm, produces a kind of moth or miller, while the proper Hessian fly is not the large, long-legged, yellow fly he describes, but a little fellow not more than an eighth of an inch long.

Drainage.—R. F. Roberts, Racine Co., Wis. This subject was treated at length in several chapters in the volume of the *Agriculturist* for 1861.—French's Farm Drainage is a work devoted to the subject, which may be had at this office for \$1.25.

Corn Brooms.—J. M. Martin, Lewistown, Pa.—In the Jan. and March numbers of the *Agriculturist* for 1860, two illustrated practical articles upon this subject were published. If you have not the back volume we can supply it, or these two numbers, at the usual rates.

Water Lime.—J. Dunn, Jr., Pa. Hydraulic or Water Lime is made from a kind of limestone which contains a considerable amount of magnesia, silica, etc. It is also known by the name of Hydraulic Cement, and is the kind used for lining cisterns, or for similar purposes.

Good Drink for Summer.—David H. Harris, Rock Island Co., Ill. We know of nothing better for a summer drink than pure, soft, cold water. In a limestone country where spring and well water is hard, or where from any reason good water could not be obtained otherwise, we should use a filtering cistern. One form of construction is described in this number, page 73.

The Demarest Sewing Machine.

To many inquirers. From what we have seen of it, we think this machine may be useful to dressmakers, or those who have much sewing to be done with a running stitch, on very thin fabrics, such as poplins, bareges, &c., but it is not adapted to general family work, such as sewing sheetings, the thicker calicos, or any heavy work.

Post Office Department "Not Guilty."

It would hardly be surprising that in sending 100,000 letters, there should be a few errors, but in view of the great number of defective letters received, we, as well as other publishers, are led to acquit the Post-Office Department of many of the sins laid to its charge. This very day we received a letter from a distant town to which it had been wrongly directed; another from the dead letter office, whither it had been sent and opened, from want of any proper direction on the outside; also two money letters entirely unsealed, but with the money all safe, however; it had passed through honest hands, and had not fallen out; also a notice from a Wisconsin Post Office, that there was a letter there for us "held for postage." The receipt of such letters are of very frequent occurrence.

The Farm for Sale, advertised in this paper, is worth looking after, we judge from the statements of the owner who informs us that it came into his hands rather against his will, he having to take it to secure some money loaned. Any one thinking of purchasing will, of course, in this case as in all other similar cases, make careful personal examination of the character of the soil, the location, the buildings, title, etc.

A Profitable Cow.—D. M. Hays, Fayette Co., Mich., writes that he has a three-quarter Durham cow, fourteen years old, which has given an average of ten quarts of milk per day, for twelve years, with the exception of two months. She has had only three calves. The youngest of these is now six years old, yet the cow at the present time yields six quarts of milk per day.

Cause of Crib-Biting.—A. S. Fradenburgh, Dutchess Co., N. Y. Horsemen differ as to the cause of crib-biting; some think it a mere habit, resulting from idleness in the stable, or learned from other horses. We incline, however, to the opinion that it proceeds from indigestion. The animal seems desirous of repelling gas from the stomach; this is a common symptom of dyspepsia. Hearty food, with insufficient exercise, and want of pure air will ultimately derange the stomach, and thus perhaps induce the habit of cribbing. The remedy in such cases would be to restore the stomach to its proper condition by giving good air, exercise, change of diet, and perhaps the use of some mild tonic.

Plank Floors and Sweeney.—David L. Phillips, Cuyahoga Co., O. Sweeney in horses is a shrinking of the muscles of the shoulder, induced by some injury which has prevented those parts from receiving their proper share of the circulation. Plank floors alone would hardly cause sweeney; but if there should be lameness or other ailment which might result in that difficulty we should prefer a well littered flooring of earth for the horse to stand upon.

The Best Bee-Hives.—D. M. Allen, Geauga Co., O. The makers of all bee-hives claim superiority for their own; we can not say which is absolutely best. Langstroth's is undoubtedly good. They can be made of any size desired. Success in bee-keeping depends more upon proper attention to the stocks, than upon the hives in which they are kept. Improvements in hives are mainly to facilitate the operations of the bee-keeper.

Tree Monuments—A Tree for Every Child.—A French Journal says that, at Thourrette, in the Department of Ain, the Cure (priest), who is nearly 80 years old, has always insisted, for at least for 30 years past, that for every child baptized by him, the parent should plant a fruit tree of some kind. The result is, that this Commune, though formerly very unproductive, now presents the appearance of an immense orchard. That Cure deserves a monument—indeed he has many of them.—The day the writer was born, a willow slip was struck into the soil in the yard in front of the log cabin. When we last saw it some years ago, it had a trunk so large that two men could scarcely embrace it, and a mass meeting could gather under the shade of its wide spreading branches. (With some of us it was not a favorite in childhood; its long slim twigs were rather too convenient on certain occasions.) When we were in college, it was proposed that the members of each successive class should plant a tree on the "campus" or college grounds. The result was, a large collection of fine shade trees, that will

yield refreshing shade for generations to come. Perhaps our own sons, and sons' sons, may find shelter under the tree planted there by the hand that writes this. We commend the hints above, to parents, and to students in institutions of learning, not excepting those in the public schools.

Catalogue of Fruits.—The Amer. Pomological Society has issued the report of the Committee on the revision of the Society's catalogue, which embraces reports from State Committees, by districts. Against the names of the different fruits are marks showing in what districts each one is recommended. The work is valuable, and we hope it will be accessible to the public. Will President Wilder please inform us on what terms copies can be obtained by those desiring them?

The New "National Almanac," just published by Geo. W. Childs, Philadelphia, is a very complete and useful volume, containing, within its 700 closely-printed pages a vast amount of statistical and other information. It gives very full details of the different departments of the Government, the army, navy, &c.; the same of the individual States; abstracts of public laws, excise tax, tariff, records of public events, religious and educational statistics, etc., etc. Price \$1.50.

Harris' Insects.—"A Treatise on Some of the Insects Injurious to Vegetation; by Thaddeus Wm. Harris, M. D., etc."—Two editions of this important work were published during the author's life, but under State auspices, and it was with difficulty that any copies could be obtained by the public. It was a capital idea in Mr. Chas. L. Flint, Secretary of the Massachusetts Board of Agriculture, to bring out an edition under circumstances which will insure a supply equal to the demand. It is published by Messrs. Crosby & Nichols, of Boston. Under the editorial supervision of Mr. Flint, the third edition is enlarged and improved, with additions from Dr. Harris' manuscripts, and with original notes by the editor. It is illustrated with many engravings drawn from nature, under the superintendence of Prof. Agassiz. The work contains 640 pages, and is published in three forms—one a superb edition, on tinted paper, at \$6; one on plain paper, with colored plates, at \$4; and one with uncolored plates, at \$3.00. In this work, in his original works on Grasses, on Milch Cows and Dairy Farming, etc., and in his constant energetic labors as Secretary of the Massachusetts Board of Agriculture, Mr. Flint is doing good service to the cause of agricultural progress.

Death of Grant Thorburn.—This well known seedsman and florist died on the 20th of January, at New-Haven, Conn., at the advanced age of 90. He came to this country when quite a young man, and was for a long time the leading florist in this city. His publications and his occasional contributions to the papers are full of interesting reminiscences of the New-York of our grandfathers. Mr. Thorburn retained his health up to the time of his death, and attributed his freedom from illness to obedience to the laws of health, and temperate habits.

Death of an Eminent Horticulturist.

Dr. W. D. Brincklé, died at Groveville, N. J., on the 16th of December last. Dr. B. occupied a prominent place among the pomologists of the country, and was Vice-President of the Pennsylvania Horticultural Society, and one of the leading members of the American Pomological Society. The writer well recollects how his first visit to the horticulturists of Philadelphia was made pleasant by the genial courtesy of the Doctor, who seemed full of enthusiasm for everything connected with his favorite pursuit. He originated a number of fruits from seed, and his name is especially identified with the Brincklé's Orange Raspberry. The President, Cnpe, Wilder, and other Raspberries, originated with him, and he was the means of bringing many of our valuable native fruits into notice. In England such a man would have a statue erected to his memory, and we hope that in this country some memorial will acknowledge the services of such public benefactors as Dr. Brincklé and all others of his class.

N. Y. State Agricultural Society.

The Annual Meeting on Feb. 11 was interesting with discussions on various questions, addresses by the acting President, Cornell, and others. Officers elected for 1863: President—Edward G. Faile, of East Chester, Westchester Co.; Vice-Presidents (One for each Judicial District.) 1. James B. Johnson, of New-York; 2. Samuel Thorne, of Washington Hollow, Dutchess Co.; 3. H. Wendall, Albany; 4. C. Boughton, Saratoga; 5. E. Merriam, Leyden, Lewis Co.; 6. E. J. Hayes, Unadilla; 7. B. M. Baker, Rochester; 8. T. C. Peters, Darien. Executive Committee—Jas. O. Sheldon, Geneva; Samuel Campbell, New-York Mills; D. D. T. Moore, Rochester; J. McGraw, McGrawville; Oscar Granger, Saratoga. Cor-

responding Secretary—Col. B. P. Johnson, Albany. Recording Secretary—E. Corning, Jr., Albany. Treasurer—L. H. Tucker, Albany.

Conn. State Agricultural Society.

—The Officers for 1863 are: President—Ephraim T. Hyde, 2d, of Stafford; Vice-Presidents—Robbins Battell, of Norfolk; D. F. Gulliver, of Norwich. Corresponding Secretary—T. S. Gnd, of West Cornwall. Recording Secretary—W. W. Stone, of New-Haven. Treasurer—F. A. Brown, of Hartford. Chemist—Prof. Samuel W. Johnson, of Yale Agricultural Department, New-Haven. Directors—Benj. H. Andrews, New-Haven Co.; Chas. M. Pond, Hartford Co.; Henry Bill, New-London Co.; Eliakim Hough, Fairfield Co.; Benj. Sunner, Windham Co.; Lemuel Hurlburt, Litchfield Co.; Henry L. Stewart, Middlesex Co.; B. R. Chamberlain, Tolland Co.

"Shall we Contract our Wool?"

So ask a considerable number of subscribers to the *Agri. culturist*. They inform us that already a considerable number of buyers are circulating through the country, offering to contract for the next clip at prices which would, until recently, have been considered very high. Wool is now selling in this market for 65 to 90 cents per pound—the coarse long grades almost as high as the fine qualities. (For latest prices, see our market reports.) It is claimed by those offering to contract, that the present rates will not continue. They may not, but they are as likely to go higher; it will depend upon the state of the currency. If gold continues at its present premium, or goes higher, wool will go up. There is not wool enough produced in the country to supply the home demand, and it cannot be imported at the present prices, while exchange stands at 170 to 175, as now, and the high duties must be paid in gold or demand-notes, which are 50 to 60 per cent., or more, above the currency. (The high tariff is certainly benefiting farmers now, if never before.) We can hardly advise, for we know not what changes in the currency may result from the legislation now under discussion in Congress. Those offering to contract for wool are likely to be best informed as to the prospects of the market, and if it will pay for them to contract, will it not be as likely to pay farmers to hold on to it?—There is another item to be taken into account. If wool goes up in price, the contractors will be sure to call for it. If it goes down, will they be as certain to do so—especially those irresponsible, peripatetic buyers who perhaps can not be found when wanted, unless it is for their interest to be on hand? If we contracted at all with any person not a resident, and not known to be responsible, we should certainly require a payment down of at least one-fourth. All contracts should be plainly stated in writing, and a duplicate copy, signed by both parties, be retained by each.

A Work on Tobacco Culture in Progress.

In response to the offers last month (page 39), a considerable number of essays have come in, and notices of many more in preparation have been received. We are therefore able to announce that a sufficient number of the best of the articles will be put in type, as soon as they can be selected, after March 1st, to make a neat, practical treatise of at least 32 pages, containing the plain directions of a large number of growers in different parts of the country. It will undoubtedly be the best available source of information on the subject of tobacco culture. The price will be about 25 cents per copy. Those desiring the work can send their orders, which will be filled as early as March 15th, and perhaps before that time. In an article on page 83 we give directions for all work needed to be performed before the printed essays will be ready.

International Agricultural Exhibition.

An Exhibition of stock and agricultural products of all kinds, and agricultural implements and machinery, will be held at Hamburg in July, from the 14th to the 20th, inclusive. The premiums offered are liberal, and are open to general competition. The city of Hamburg is readily accessible from the great agricultural districts of Europe, and as the German agricultural societies, as well as other European societies, co-operate with the Local Committee, there is every prospect that the Exhibition will be an important one. No machinery will be allowed on exhibition which is not directly or indirectly connected with agriculture. It is hoped that our inventors and manufacturers of agricultural implements will see that this important branch of American industry is well represented at this exhibition. Not only our reapers and mowers, and such large machines, have

proved superior to those of European manufacture, but the small tools, like hoes, forks, &c., were so far in advance of those in general use by European farmers, that it should be a matter of national pride to show to the agriculturists of Europe the progress we have made in this respect. Those who wish to exhibit farm products or implements, can obtain circulars from the American Agents, whose advertisement may be found in another column. There is direct communication, by steamers, between New-York and Hamburg, and the latter being a free port, there will be no duties to pay, or delays at the Custom-House. The time during which applications can be made is limited to the 15th of April.

The Eighth U. S. Census—Interesting Agricultural Statistics.

[Several items from the last Census have already been printed in this journal. A very complete, condensed exhibit of the population of the entire country, showing at a glance, the number in each State, increase, etc., prepared for and published in the August *Agriculturist*, 1861, has been widely copied, and is still going the rounds, uncredited. The agricultural statistics were not published until recently, and we now present a series of interesting tables, with accompanying remarks, prepared for this journal by our correspondent, Daniel J. Thomas Esq., of Sacramento, Cal., for which he will please accept our thanks.—ED.]

All readers of the *American Agriculturist*, whether farmers or not, will be interested in fully understanding the material value and pecuniary importance of the great farming interests of this country; the rapidity with which land is being brought under cultivation, and the great increase of the agricultural productions of the country. These tables have been collected from Superintendent Kennedy's "Preliminary Report on the Eighth Census." The work has involved considerable labor—but a labor of love, as well as of interest to the writer. The general facts exhibited are such as every citizen, and particularly every farmer, should be proud of. No one can examine them without feeling that notwithstanding her troubles, the destiny of our Nation is higher and still higher, onward and still onward until the illimitableness of her agricultural wealth shall astonish the world more than now does the magnitude of her Minerva-born army, or the might of her impromptu navy. (We should like to tell the proportion that farmers, planters, and rancheros, bear to the other classes of society, but the present volume does not give the professions, trades, and occupations. We must therefore wait for the complete report.

Among the most important and most pleasing exhibits are these: In 1850 there were only 113,032,614 acres of improved land in the United States: In 1860 there was 163,261,389 acres, making 50,228,775 acres brought under cultivation during the ten years, or rather more than five millions of acres per annum of wild lands rendered productive! Think what must be the future of a Nation that yearly adds five millions of acres to her feeding capacity! Yet, important as is this increase in the amount of cultivated lands, the tables show a still mightier element of success. It is book-farming—the influence of such papers as the *American Agriculturist* and its coadjutors in disseminating both theoretical and practical agricultural knowledge. Are the *Agriculturist*, and other bucolic papers, mentioned in the report? Not directly—; but it is stated there that the value of agricultural implements manufactured in 1860 was \$17,802,514, against \$6,842,611 in 1850, being \$10,959,903 more in the former than in the latter year. The increase of land brought under cultivation is about 45 per cent.; the increased yearly requirements for implements is about 160 per cent. Could there be any better or more perfect report in favor of the advantages of book-farming

or of the agricultural press? We think not. The value of implements used by farmers in 1860 was ninety-five millions of dollars more than the value of those on hand in 1850. These facts naturally lead us to look for an increased value in our farms—and we find it. While but forty-five per cent. more land has been brought into cultivation, the whole value of the land cultivated, more than doubled. Could there be a better report in favor of "book-farming" as it is called?

The following is the showing for the principal

GRAIN CROPS.—PRODUCT.			
Kind.	1860. Bushels.	1850. Bushels.	Increase.
Wheat.....	100,455,944	171,183,381	70,697,437
Rye.....	14,188,813	20,976,286	6,787,473
Indian Corn.....	592,071,104	830,451,707	248,380,603
Buckwheat.....	8,956,912	17,664,914	8,708,002
Oats.....	116,584,179	172,554,688	55,970,509
*Barley.....	5,167,015	15,635,119	10,468,104

Incr'd yearly production of grain in 10 years..471,012,128

The grain crops as between the loyal States and the twelve seceding States and Territories viz.: Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, Tennessee, Texas, Virginia, and New Mexico, stands:

GRAIN CROP AS TO LOCALITY.			
Kind.	Loyal States. bushels.	Sec'd States. bushels.	Excess in L. S., bush.
Wheat.....	144,770,275	26,413,106	118,357,169
Rye.....	18,801,953	2,174,333	16,627,620
Indian Corn.....	549,076,288	281,375,419	267,700,869
Buckwheat.....	17,127,796	537,148	16,590,678
Oats.....	152,626,770	19,927,918	132,698,852
Barley.....	15,448,713	186,406	15,262,307
Total.....	897,851,795	330,614,300	567,237,495

In connection with the foregoing the following table, which we have carefully prepared, of the population and classes of inhabitants of the two sections, will be exceedingly interesting to those who have leisure to study it, and who will take the trouble to institute comparisons.

TABLE OF POPULATION OF THE UNITED STATES.				
	Loyal S.	Rebel S.	Loyal Ex.	Rebel Ex.
White.....	21,150,760	5,532,417	14,618,343	
Free Negroes*.....	378,295	132,815	245,480	
Slaves.....	432,650	3,521,110		3,088,460
Total.....	21,961,705	9,186,342	12,775,363	

* In this are included 23,140 Chinese and 14,555 Mission Indians of California, making a total of 37,695 in these classes.

A curious feature disclosed by the census is, that two of the slave States contain the most free negroes. Maryland has 83,942, Virginia 58,442; then Pennsylvania follows with 56,849, New-York 49,005, Ohio 36,673, North Carolina, another slave State, being sixth on the list with 30,463.—But to return to agricultural statistics.

VALUE OF FLOUR AND MEAL PRODUCED.		
	Loyal States.	Seceding States.
1860.....	\$192,002,722	\$31,142,647
1850.....	119,315,989	16,581,817
Increase.....	\$72,686,733	\$14,560,830

This gives about \$8.75 worth of flour and meal for every inhabitant of the loyal States, against about \$3.40 for the seceding States.

The bean, pea, root and seed crops increased throughout the country during the decade thus:

PRODUCTION.			
Kind.	1850. Bushels.	1860. Bushels.	Increase.
Peas and Beans....	9,219,901	15,188,013	5,968,112
Irish Potatoes....	65,797,896	110,571,201	44,773,305
Sweet Potatoes....	38,268,148	41,606,302	3,338,154
Flax Seed.....	562,312	611,927	49,615
Clover Seed.....	468,978	929,010	460,032
Grass Seed.....	416,831	900,386	483,555

The above shows that the annual production of Flax Seed is now about fifty thousand bushels greater than it was ten years ago. This increase, though fair, is very small compared with almost everything else; and when we look at the production of flax itself the matter is a very great deal worse. In 1850 the dressed flax amounted to 7,709,676 pounds; in 1860 it was but 3,783,079 pounds,—decrease in the yearly product of nearly four million pounds. This should not be. Some means must be found to make flax raising for the fibre a paying crop. Silk cocoons, too, fell off from a yearly supply of 10,843 lbs. to 6,562 lbs. Rice is also one of the retrograding

crops. It was about 4,000 tons less in 1860 than in 1850. The figures are: 215,313,497 lbs. reported in 1850 against 187,140,173 lbs. in 1860.

The Cotton crop of 1860 was 5,196,944 bales, of 400 lbs. each, or something over two thousand millions (2,000,000,000) of pounds, against 2,445,793 bales (978,317,200 lbs.) in 1850. The yearly production of hemp is about seventy thousand tons greater now than ten years ago. In 1850 we had 34,871 tons, and in 1860, 104,590 tons.

	1850—lbs.	1860—lbs.	Increase.
Butter.....	513,345,306	460,509,854	147,164,548
Cheese.....	105,533,893	105,875,135	39,242
Hops.....	3,497,029	11,010,012	7,512,983
Sugar (Cane).....	237,153,000	302,205,060	65,052,000
Sugar (Maple).....	34,253,436	38,863,884	4,610,448

The following agricultural productions, in which we include the value of farms, of agricultural implements in use, of agricultural implements manufactured during the year, and the value of home manufactures (goods made on the farm and in the household) are returned in dollars. Of these, "home manufactures" are the only things that decreased—labor gradually finding better pecuniary employment than competing with the steam engine and machinery to make "homespun." The census of 1860 gave to this branch only \$24,358,222, against \$27,493,644 in 1850—a falling off of \$3,135,422.

The other things measured in dollars are:

	1850.	1860.	Increase.
Live Stock.....	\$544,180,516	\$1,107,490,216	\$563,310,700
Farms, Value.....	\$3,271,575,426	6,650,872,507	3,379,297,081
Farm Implem's.....	151,587,638	247,027,496	95,438,858
Orchard Prod's.....	7,723,186	19,759,361	12,036,175
Market Gard's.....	5,280,030	15,541,627	10,261,597
Slaughter'd Anim's.....	111,703,142	212,871,653	101,168,511
Agri'l Imp. made.....	6,842,611	17,802,514	10,959,903

We find Hay and Hemp returned by the ton:

	1850—tons.	1860—tons.	Increase.
Hay.....	13,838,642	19,129,128	5,291,586
Hemp.....	34,871	104,590	69,719

The liquid products are given in gallons thus:

	1850—Galls.	1860—Galls.	Increase.
Cane Molasses....	12,700,991	16,337,080	3,636,089
Sorghum Molasses.....		7,235,025	7,235,025
Maple Molasses.....	not given.	1,944,594	
*Wine.....	221,249	1,860,008	1,638,759

* Of this quantity Ohio furnished 562,640 gallons, California 494,516 gallons, and Kentucky 179,949 gallons.

The Live Stock returns require an explanation. Hitherto the census blanks provided for accounts of domestic animals only from persons filling up the agricultural schedules, which, of course, left out the animals owned by those engaged in other pursuits. Seeing this deficit, Superintendent Kennedy ordered supplementary returns of the previously omitted stock. We have arranged our condensed tables to show both classes. The ratio of increase will be best gathered by comparing the first two columns; the difference is shown in the fifth column.

	Owned by farmers in 1850.	Owned by farmers in 1860.	Owned by others in 1860.	Increase in total num- ber reported
Horses.....	4,336,719	6,115,458	1,185,514	
Mules and Asses.....	559,331	1,129,553	166,786	
Hogs.....	30,354,213	32,555,267	3,467,905	
Sheep.....	21,723,220	23,317,756	1,564,810	
Milch Cows.....	6,385,094	8,728,862	1,200,000

Other Neat Cattle.....	16,518,400	4,378,331	6,225,340	

The facts above set forth are very suggestive of thought, and worthy of study by not only the farmer, but by the mechanic and artisan, the merchant and manufacturer, the politician and the statesman—in fact by all classes. We have not space left for conclusions and inferences, but may, perhaps, resume the subject hereafter. T.

Rough Roads.

That these are unpleasant to ride upon, no one will deny. They torture a rheumatic or nervous man beyond peaceful endurance. They obstruct business, they interfere with sociability between neighbors, and with that well-known enjoyment which comes from riding, whether in carriage or saddle. They make horse-life painful; and, more than this, they are *expensive*. Ask any observing man who has lived in different parts of the country, and he will testify that wagons last much longer in light, sandy soils, than in clayey or stony lands. When a fast-moving vehicle strikes a stone, it receives a serious blow. The tire is battered,

joints are started, the harness strained, and the horse strained too, if not the rider. Now suppose such shocks repeated several times a day, and throughout the year, the result must be something important. At least, so the bills at the blacksmith's and the harness-maker's will testify.

One who is tolerably quick at figures, might reckon the cost of a single fixed stone in the highway for a year. And if of one stone, what of many thousands? An estimate of the cost of stony roads to this State was once made by a writer in the Albany Cultivator, substantially as follows: There are 60,000 miles of public highway in the State, 50,000 of which are more or less stony. It would cost about \$25,000 a year to clear out the stones. The aggregate value of buggies and farm wagons is about \$60,000,000. If the roads were kept smooth and clear of stones, it would be a saving of about eight per cent. of wear and tear, or nearly \$5,000,000. Now, taking out the cost of cleaning the roads, it would leave us a gain of \$4,975,000, annually, a sum not to be despised in these dark days! [This estimate is an exaggerated one; less than half a dollar a mile is allowed for clearing up the roads; but make the cost average \$10 a mile, and the profit would still be very large. The moral of this is, that it would pay well for the inhabitants of every neighborhood to spend a few days annually, with crowbar and pickaxe, in removing imbedded stones, and in taking all loose stones from the roadway.—Ed.]

"Fining" Manure.

An English gardener of the writer's acquaintance makes a great deal of what he calls "Fining Manure." He means breaking up the lumps, tearing in pieces the long, strawy parts, and bringing it all into such a fine state that it can be thoroughly mixed with the particles of the soil. Having broken it up, he mixes it with ashes, leaves, sawdust, tanbark, and all the refuse of his garden, laying it up in thin layers. When it has become partly decomposed, he overhauls it, turning it over with the shovel, and making it one homogeneous mass. After the heap has lain a few months, it gets another working, when it is thoroughly "fined" and ready for use anywhere. He is a very successful gardener, and ascribes no small part of his success to this careful pre-

paration of his manure. Farmers and others may learn a hint from his example. It is plain that coarse, lumpy manure cannot benefit land as much as that which is broken up and finely diffused through it. One reason why liquid manure and guano act so efficaciously, is because they are so minutely divided among the soil.

Aydelott's Automatic Flood Fence.

A correspondent in New Albany, Ind., who signs himself "Q in a corner," sends an account of a fence that he saw on the farm of Geo. K. Aydelott Esq. in Mead Co., Ky. Every one who has had experience with fences upon lands liable to overflow in time of a freshet, will be glad to know of this simple and, according to our correspondent, very effective plan for fencing such places. The fence he saw was upon a steep bank of the Ohio River, where it was used for a lane by which the cattle went to the river to drink. It was of some 50 sections, had been in use for three years, and though it had been frequently inundated, it had not cost fifty cents for repairs. The structure will be readily understood from the engraving: the posts *a*, are of locust or cedar, 4 feet long, and about 6x3 inches; these are sunk three feet in the ground. Near the bottom of the posts, pins *b*, 2 inches in diameter and 2 feet long, are driven, and upon the projecting ends of these, stones are placed. These, with the earth well rammed in, serve to anchor the fence; the oak studs *c*, are 4 feet long, of 4x4 stuff, to which the slats of the fence are nailed, forming a section of the fence. The pins *d*, are of inch iron, and are put loosely through the lower ends of the studs and the upper ends of the posts, so as to form a hinge. The sections are kept upright either by braces, or by stakes with a rider as seen in the left hand figure. When the water rises, the supports break away or float off and the panel falls down, as shown in the right hand figure. (The joints are not engraved quite right.) It presents little resistance to the current, and remains safe until the water subsides, when it is readily set up again.

Benefits of Irrigation.

The benefits of irrigation, or conducting a stream of water over meadow or other land, are not, as some have supposed, confined to locations subject to drouth. It is not so much the water that the land needs, as what the water contains. Streams are not only fed by springs, but they receive much surface water, especially during violent showers, and long continued rains. In its passage over the soil, the water takes up, both mechanically and chemically, a large portion of valuable fertilizing matter. This can readily be seen when the

stream is turbid from recent storms. The best proof, however, of the presence of large amounts of such matter in running streams is found in the rich deposits of muck where the current of the stream is very sluggish, which allows much of the suspended matter to fall to the bottom. The accumulations in such places frequently become so great, as to change the channel of the stream, as is seen where deltas are formed at the mouths of rivers. Now if the water of a stream is made to rest a while upon a meadow, a large part of its impurities will be left just where they are wanted to fertilize the growing grass. This is the theory of irrigation as needed in most parts of this country. The manner of effecting it will depend upon the positions of the stream and fields. Hundreds of brooks that are now idling through the field, yielding nothing but an occasional drink to the cattle, might be made to contribute largely toward enriching the farm.

An Improved Filtering Cistern.

Several plans for filtering cisterns have heretofore been published in the *Agriculturist*, all possessing some good features, but not readily applicable to cisterns already constructed. The one shown below, was designed to meet this want, and it may be of service to others desirous of obtaining the best kind of water for all purposes, but for whom it may not be convenient to build the separate cisterns usually recommended.

The engraving represents a vertical section of the cistern and filtering arrangement. *C*, shows the main reservoir, which receives the water. A semicircular well of brick, *W*, two feet in diameter, is built against the wall of the main cistern. The bricks are laid in hydraulic cement, and the wall is cemented on both sides. The

water flows into this well through a pipe, *P*, from the bottom of the filter, *F*, and is drawn out through the tube, *T*, by a pump at the top of the cistern. The filter, *F*, consists of a brick compartment or box, 18 inches in length, width, and height. It is built along the side of the main cistern, the wall of the well forming one end of the box. The tube connecting the filter with the well, is of galvanized iron, having a cap punched with holes, on the end entering the filter. The filtering materials are, commencing at the well, first a layer of gravel 3 inches thick; then a thickness of cotton flannel; next 7 inches of pounded charcoal, made about half the size of peas; 5 inches of sand, and 3 inches of gravel for the last layer. These layers are placed before the box is covered, and are made vertical, as shown in the engraving, instead of horizontal in the usual manner. Before filling the filter, fit a plate of galvanized iron punctured with fine holes, to form the outer end of

the box, and fasten it in place. The filtering materials can then be readily put in by using slips of sheet iron or tin to keep them from mixing while being introduced. The slips can be gradually drawn out as the filling proceeds. When filled, the box may be covered with flat stones, or with a sheet of galvanized iron. All joints should be cemented tightly.

The object of placing the layers vertically, is to prevent the accumulation of sediment upon the top layer of the filter. With the arrangement described above, much of the deposit will fall to the bottom of the cistern, at the foot of the filter. Another advantage is that the well will be supplied with water as long as any remains in the cistern, for it will keep at the same level in both divisions.

About Buying a Farm.

"Reading the *Agriculturist* has made a farmer of me in theory, and now I intend to become one in practice; please give me some counsel in relation to purchasing. Where? how much? what kind of soil? etc., in short, whatever you think should be suggested to one in my circumstances." So writes a city subscriber, and many letters of similar import are awaiting a reply.

First, then, it may not be advisable to buy at all. Farming on paper is easy, pleasant, and gives a good show of profit; actual cultivation of the soil may be as enjoyable and remunerative, provided a man knows how to accomplish work easily, is enthusiastic in the business, and has brains and experience to plan wisely. It is not always best for men of middle age, brought up to other callings, and possessing limited capital, to buy a farm. It requires experience and skill as well as hard work, to lift a mortgage, and most novices will be disheartened before it can be accomplished. Young men of nerve, whose habits of life are not yet fully fixed, have better prospects of success; yet in their case it would be wiser to work a few years under instructions, to gain at least the rudiments of cultivation, before involving themselves by purchasing land.

But supposing the cost to have been counted, and a decision made, *where* shall he buy? The proper answer depends upon the branch of agriculture which is to be made prominent, whether dairying, raising of stock, grain, garden vegetables, or fruit. For the last two, nearness to market is almost indispensable; it is desirable in all cases. For other purposes, it is safe to locate where others are successfully engaged in the kind of business desired. Unlike manufacturing, there is little danger from competition in any particular locality; one must leave a farm before another can enter upon it; though on the open prairie there is room for all.

Buy land of no man without thorough personal inspection. If inexperienced, secure the services of a friend competent to make the examination. Ascertain the character of the neighboring society and the distance from schools and churches. Give a thorough examination to the soil. The growing crops may not be a fair test of the capacity of the land. An unpropitious season, or an unusually favorable one, may lead to a wrong estimate. Dig down through the surface soil, in various fields, and note its depth. Farms covering equal areas may differ by more than one-half in amount of serviceable soil—one being scarcely four inches, the other twelve or more inches deep. Observe the character of the subsoil, whether hard pan, requiring draining, or gravel unable to bear drouth. A mo-

derately firm, deep loam is desirable for tillage, and one containing limestone, is generally the best, especially for wheat, corn, and orchard purposes. If we had capital to drain and subsoil well, we should not object to a stiff loam, approaching clay, for such soils are permanent, can hardly be "worn out," and if well drained and thoroughly worked, they make the best use of manure, are less affected by drouths, and give a good yield of hay, as well as of other crops.

Examine the slope of the fields, whether to the north where Winter will linger, or to the warm south, where Spring loves to show her first favors. Are the fields well laid out and fenced? Well watered? Are there sufficient buildings, and what is their condition? If the capacities of a farm be sufficient, it may sometimes be bought to advantage, although "a little run down." Proper management will bring up a naturally good soil, and money may often be made by putting such a place into good heart. But no one should attempt such an operation without the most careful estimate of the amount needed, and the reasonable assurance that it will not be likely to exceed his available capital.

When a favorable decision is made, engage the services of a reliable lawyer to search the title. Fifty or a hundred dollars expended in this way would have saved many a man from more than ten times that amount of loss. The writer has now in mind the case of a hard-working farmer whose earnings for years were lost by neglect of this precaution. Finally, be prepared to work hard, to meet and overcome unlooked-for difficulties which can only be known by experience, and to be content with small but steady gains, and a life of peaceful independence.

Two Kinds of Sugar—Sweetening from Sorghum—Evaporators.

There are two leading kinds of sugar, known as *cane sugar*, and *grape sugar*. Cane sugar is obtained from the southern cane, from the sap of the maple, from the juice of beets, etc. Grape sugar is found in raisins, in those fruits and plants generally which possess sour or acid juices, and in honey. It can also be produced artificially from starch, from woody fibre, from cotton, etc. Cane sugar contains 12 atoms of carbon, united with the elements of 11 atoms of water, while grape sugar contains 12 atoms of carbon and 14 atoms of water. We can change cane sugar into grape sugar by a chemical process, which will cause the former to take up the extra atoms of water in chemical combination. But cane sugar cannot be produced artificially. It is only made by some secret process of Nature within the plants themselves. Cane sugar readily takes a solid form of regular six-sided hard crystals. Grape sugar crystallizes slowly and imperfectly, as is the case with solidified honey, and the crystals are irregular, ill-defined, and usually in needle-shaped tufts. A third kind of sugar, sometimes called *fruit sugar*, is entirely uncrystallizable, like that found in molasses, etc.

The above distinctions are important, in reference to the new plant, Sorghum. If the main portion of the sweet element be grape sugar, we cannot hope for great success in manufacturing solid cane sugar from it, while it may be a source of sweetening in the form of molasses and grape sugar; for, as stated above, grape sugar cannot be transformed into the crystallizable cane sugar. A scientific correspondent of the *American Agriculturist* offers the following suggestions. We cannot say how near right he

may be, but his suggestions are worthy of investigation. He says: "It is amusing to note the claims put forth by the different makers of evaporators, with regard to the superior power their particular inventions have over all others, to extract sugar from sorghum. The fact is, that sorghum and imphee contain very little sugar that will crystallize, but a great deal that is uncrystallizable; and no evaporator can produce any more of the former, than the juice naturally contains. While crystallizable sugar can readily be converted into the other kind, there is no process yet known by which the operation can be reversed. Exposure to heat in contact with the air will convert cane sugar into the uncrystallizable sort, or molasses. One of the greatest improvements in sugar refining is the vacuum-pan, a closed evaporator from which the air is pumped. In this the syrup is evaporated without coming in contact with the air, and at a much lower temperature than if exposed. It is very apparent that the value of sorghum and its allies, as a source of sugar, will never be increased by the inventive genius of evaporator makers. We must look to some new variety, or remarkable improvement in the old, before we can get a large amount of crystallizable sugar from this source."

How Cotton was Grown in Illinois.

The Rev. J. A. Bent, of Hazleton, Washington Co., Ill., whose sample of 10 lbs. of cotton is on exhibition at the office of the *American Agriculturist*, sends the following statement of his experience in growing cotton. His locality is in about the latitude of St. Louis. We should be pleased to have the experience of those who have successfully grown cotton farther north:

"I was unable to plant until about May 20th. I prepared two pieces of land, one of an acre, and the other of half an acre. The former had been in cultivation several years, the latter was newly rotted prairie sod. The old ground was prepared as if for corn—except that the rows, 3½ feet apart, were raised a little by turning two light furrows toward each other. The seed, one bushel to the acre, was rolled in moistened ashes immediately before being planted, so as to increase the ease of scattering it uniformly in the furrow; it was covered with a hoe one inch deep. In the South, a larger quantity is usually planted, and the plants are thinned out or cut off when hoed, and in the decomposition of their roots, they serve as a manure to those that remain; by this means a good start is rendered comparatively certain. My seed came up well, but in spots I lost not a few plants by the ravages of grubs or worms. When the plants were about four inches high, they were hoed, or rather the weeds (principally purslane) were scraped away from the cotton to the middle of the space between the rows. When the plants had grown to be about a foot high, they were plowed out, first turning the earth away from, and then throwing it back to them. The plants were then thinned to about 16 inches apart in the row, where they were too thick. The first blossoms appeared about the 20th of July. The plants when full grown were from 2 to 5 feet in height, and contained from 15 to 40 bolls each. They opened for picking early in October, and up to December the cotton was good. Since then the cotton has been yellowish, and much of it not perfectly developed. The cotton on the smaller piece received less attention, as there were no weeds; it yielded the best. Owing to my failure in getting a perfect stand, I really

had what might be called a stand for one acre. The amount of good cotton actually picked, up to this time, is about three hundred pounds, or what is sufficient to make 75 lbs. of ginned cotton. Had I been able to have planted mine three weeks earlier, I think there would have been at least enough to have made one hundred pounds, which as the prices now are for Upland Middlings in New-York, would be worth there \$68.

The charge for ginning cotton is usually, I believe, one tenth. The expense of cultivating and securing an acre would be about as follows:

Plowing and laying off, and planting.....	\$2.00
1½ bushels of seed (say at present).....	1.50
Hoeing, thinning, and cultivating.....	3.00
Picking.....	4.00
The expense of ginning, if a gin is near, say.....	5.00
	\$15.50

Worth of Cotton in N. Y. at present rates as above. 68.00
Net profit on an acre.....\$52.50

There has been much more cotton raised in Southern Illinois this year than usual. The prospect now is, that more will be planted next Spring. The short staple, or Upland variety, is the kind that can be depended on to do well. To those who are willing to attend to the business *thoroughly*, I would say, as the result of my experience and observation, that it will pay well to have a field of cotton at the present prices."

[The above estimates are based upon an unprecedented price for cotton. What is here reckoned at 68 cents per lb., has usually run from 8 to 13 cents per lb., and at these prices the cotton crop would be raised at a loss. There is little prospect, however, that cotton will sink below 20 or 25 cents for a year to come.—Ed.]

Beet Sugar in Ohio.

In France, and in some parts of Germany, a very large amount of cane sugar is prepared from the juice of sugar beets. Several attempts were made a few years ago to introduce the process in this country, but without sufficient success to induce the experimenters to continue their efforts; and we have been in doubt whether, owing to the difference in climate and the great cost of labor, the manufacture of beet sugar would ever be profitable here, especially while we have so large an area at the South adapted to the growth of the American sugar-cane. Mr. Klippart, Corresponding Secretary of the Ohio State Board of Agriculture, reports at length upon experiments made last season by Prof. Mot, near Newark, Licking County, which seem to indicate success, and Mr. K. speaks quite sanguinely. We extract a few items from the detailed report. Ten acres of old corn and potato land were prepared by deep plowing, only one acre (of the potato land) being subsoiled. The seed planted was of two kinds, the "Vilmorin Improved" and the "Imperial," the former being much the best. The yield of the entire ten acres is estimated at about 190 tons. The acre subsoiled produced about six times as large a crop as an acre in any other part of the field not thus prepared. The sugar was manufactured by simple and somewhat imperfect machinery, the roots being first reduced to pulp, by means of a revolving grater, and pressed. One thousand pounds of beets yielded 78 gallons of juice. The juice was treated with "certain chemicals," evaporated, filtered through bone-black, and again evaporated and set aside to crystallize. The result was a very excellent article of brown sugar, obtained at an expense of four cents per pound. The refuse pulp was found to be an excellent food for cows. A certain portion of the process is kept secret, but there is no doubt that the method employed by

the beet sugar manufacturers of France is as perfect as any yet known. They add lime-water to the juice, and then remove the lime by means of ammonia-alum. The manufacture of sugar requires much more care and practical knowledge than it does to make syrup, and if it is found profitable to enter into the production of beet sugar in this country, no doubt the labor will be divided between the farmers who produce the roots and the establishments for working them up. The larger these manfactories, the greater will be the economy, and the consequent profits to both grower and manufacturer.

Do Potatoes Mix in the Hill?

This subject is again brought to our notice by George K. Robinson, of Canada East, and J. B. Wolff, of Colorado Territory. The former having found a red and a white potato on the same plant, and the latter had a "double potato," one half deep blue and the other half yellow, with pink eyes. The only way in which varieties of potatoes can cross or mix, is by the fertilizing of the flower of one sort by the pollen of another; the seed of those thus fertilized would be very apt to produce cross-breeds. It seems very unlikely that the cross impregnation of the flower should affect the character of the tuber, and we can not admit it until direct experiments have proved it to be the case. We have no doubt that potatoes may vary or sport. The sorts in cultivation are themselves sports, or it may be crosses of different varieties, having the blood, so to speak, of different kinds in them. It is not strange that under favoring circumstances these varieties should vary, or that some peculiarity of one of the ancestors should break out and become predominant.

Why Seeds Fail—Practical Hints.

Frequent failures are made in cultivation, which are unjustly charged to the seedsmen. Seeds are sown, they do not come up, and they are set down as old or imperfect. While such seeds are doubtless sold by some, our experience is that respectable seedsmen generally send out reliable seeds, and that the want of success is oftener the fault of the sower. In treating of the vitality of seeds in the February *Agriculturist*, it was shown that there was no general rule as to the time that seeds would keep: so, seeds after being sown, differ as to their power of resisting decay if the circumstances are unfavorable to their immediate germination. Three conditions are necessary to the growth of all seeds, viz: air, moisture, and a sufficient temperature. Any one of these failing, the seeds will not grow. The amount of heat required for germination varies greatly with different seeds; those of the common chickweed will start at a temperature just above freezing, while those of some tropical plants require 75 or 80 degrees. The seeds of the plants commonly cultivated, germinate at a temperature of 50 to 60 degrees. Moisture is required not only to soften the seed coat, but to enable the germ to grow, and too little or too much is equally fatal to success. If the soil is too dry, the seeds remain unchanged; and if an excess of moisture is present, the seeds, if delicate, will decay. In well drained soil the proper amount of water is held by capillary attraction. The third requisite, air, is always present in recently worked soil.—All the conditions being favorable, there is a great difference in the time that seeds require for germination. Placed under similar

circumstances, it has been found that wheat and millet germinate in one day, beans, radishes and turnips in two, and lettuce in four days, while melons and cucumbers require five or six, and parsley thirty or forty days. The seeds of some trees and shrubs remain in the ground one, and even two years before they germinate. The common causes of failure with good seeds are: too deep or too early sowing, and excess of moisture. When small seeds are planted too deeply, the vitality of the germ is exhausted before it can reach the light and air necessary to its growth; such seeds should be barely covered with soil, and if there is danger of the surface becoming too dry it should be shaded. Very small seeds may be sprinkled on nicely prepared soil, and then lay a board upon the surface until they start. When sowing is done too early, the ground is too cold, and many seeds rot before it becomes of a proper temperature to cause germination. Too much moisture in the soil excludes the necessary air, and this one of the requisites being wanting, the seeds decay.

For the American Agriculturist.

Will Poultry Pay?

Last year I furnished for the *Agriculturist* a full account of my poultry keeping, mode of management, etc., for the year ending 1861, which was published in the Feb. and March Nos., vol. 21, pages 41 and 74. Having just closed up my accounts, I send a report for the year 1862:

Stock on hand Jan. 1, 1862: three cocks and 72 hens; they laid in Jan. 332 eggs; Feb., 446; March, 973; April, 1,013; May, 982; June, 988; July, 813; Aug., 818; Sept., 614; Oct., 399; Nov., 466; Dec., 383 eggs—total, 8,227. In bulk equal to 8½ bbls., (packed for market); in weight 1,030 lbs. During the year there died of the old stock 18, killed of the old stock 27, chicks killed 32—on hand Jan. 1st, 1863, 105, young and old, to be reduced to 75 head. All the old stock should have been killed off before the moulting season, as the March hatched chicks begin to lay about that time. This arrangement keeps the stock young and vigorous; and with proper care and attention, ensures a good supply of eggs at all seasons.

It will be seen that in Oct., Nov., Dec., and Jan., when eggs are scarce, they gave a good supply. The whole year's account stands thus:

Jan. 1, '62. Stock on hand, 75 head, at 5 lbs. each.....	375
32 chicks killed, at 1½ lbs each, dressed.....	48
27 old hens killed, 4 lbs. each, dressed.....	108
Increase on hand, Dec. 31, '62, 80 head at 5 lbs. each 150	
Eggs collected during the year (in lbs.).....	1,030
Total.....	1,711
75 head, stock for the new year.....	375
Balance, or pounds produced.....	1,336

Each hen has produced more than three times her weight in eggs alone, and it is easy to see the amount of food produced in a year from a stock of 72 hens, reduced by death to an average of 63. Deduct loss for dressing for market, 136 lbs., and we have left 1,200 lbs., as the product of the year—besides having a new stock to start with for the coming year.

It is a pretty large farmer that lays up 1,200 lbs. of pork, and yet most people will persist in keeping one or more pigs—the flesh of which is turned into salt food for the most of the year—when poultry furnish daily a supply of fresh and excellent food, and of a kind, too, if more than is required for family use, which can be readily exchanged for cash or other products. The advantage seems to be decidedly in favor of "Barn-Yard Pheasants" over "Gutter Snipes."

Staten Island, N. Y.

J. C. THOMPSON.

Manure-Saving Barn-Yard.

W. F. Quinby, Newcastle Co., Del., sends to the *American Agriculturist* his plan for saving manure in the barn-yard. He says, "the soil should be underdrained, then place a layer of straw, C, say one foot thick on the surface; next to this a

foot of earth, B, [we prefer muck if obtainable. Ed.] and on top of this, straw, A, to any desired depth. The lowest layer of straw prevents the earth, B, from sticking to the bottom, and allows the filtered water to pass off. The earth acts as a filter, and there is no better than clay, which absorbs all the alkali and allows the water to pass off nearly pure. The upper straw, C, prevents the earth from being tramped into holes, and is converted into manure. At the proper season, all can be hauled out together for use. This plan would probably treble the usual amount of manure. It may be a good deal of trouble to arrange all this, but there is no use in calling anything trouble, in these days, that pays; and increasing manure will pay."

For the *American Agriculturist*.

One Cow to an Acre of Land.

I have heard of farmers who could keep one cow, or its equal, for every acre of land owned. How many who have fifty or one hundred acres, think they could keep 50 or 100 head of cattle? To show how it might be done, I will propose an experiment on ten acres. Stock can be kept on a variety of food, as roots, grain, and hay, better than on hay alone. Suppose five acres of the ten, to be in meadow. I would plant two acres with corn, one with beets, and sow two with corn for soiling or feeding out green. Commencing, say on the 10th of June, keep the stock in the stable and yard, mow the grass, and bring it to them. I think one acre, if part in clover, so that it could be cut the second time, would keep the 10 head from June 10th to July 15th. By this time, the corn which was sowed May 10th, would do to begin to cut, and I think from past experience, that the two acres of sowed corn would furnish plenty of feed to the 15th of October. If not, I would thin the acre of beets (which might be planted rather thickly) and feed them out between meals. From Oct. 15 to Nov. 15, feed the stalks from the planted corn, and the tops of the beets, which would by this time be fit to pull and store for Winter.

Now for the next six months, or from the middle of November to the middle of May, there would be hay from four acres of meadow, say 10 tons; one acre of beets, 1000 bushels; two acres of corn 150 bushels. That would furnish each animal for the Winter (200 days) one ton of hay, 100 bushels of beets, and 15 bushels of corn; or 10 lbs. of hay, $\frac{1}{2}$ bushel of beets, and nearly three quarts of meal per day. No doubt, stock would come out good in the Spring with that feed. There remains the month from May 15th, to the 10th or 15th of June to provide for. It was supposed that the cutting of the sowed corn might be commenced in July: by the 1st of September quite a piece of it would be cut

off; this I would sow with rye and grass seed. As frost usually occurs by October 1st, the sowed corn should all be cut before that time, and the remainder of the piece be sowed with rye and grass seed. This rye would do to begin to cut by the middle of May, and last until the grass could be mowed again. As the rye is cut off, I would begin to sow corn again. Some will say that to produce 1000 bushels of beets to the acre, or 75 bushels of corn, or $2\frac{1}{2}$ tons of hay, will require rich land; but if stock be kept up the year round, a large amount of available manure can be made, which I consider one of the greatest advantages of the soiling system. Last season I sowed 16 rods of ground with corn, the 10th of June, and it supplied one cow with a good armful twice a day for 10 weeks. In my statement above, I have allowed 32 rods of sowed corn for each animal, in order to have some left to cure for feeding after early frosts.

Notes on Flax Culture...II.

The time required for flax to ripen will depend considerably upon the character of the soil, and the weather during the season: between three and four months from the sowing is the average. When the leaves turn yellow and the last blooms are disappearing, the crop should be examined every day or two, to ascertain the degree of ripeness. It is fit to pull when the stalk is of a yellowish tinge, the leaves having mainly fallen off, and the center boll become of a brown color. Another test recommended, is to select the ripest seed capsule on an average stalk, and cut through it; when the seeds have changed from the white milky substance they usually show, to a greenish color, and are pretty firm, the flax is fit to pull. If the straw be left standing until all the seed is fully matured, the fibers are harsh and brittle. If the proper time be observed, the seeds though not quite ripened when gathered, will be perfected by the sap remaining in the stalk after it is harvested. The straw is usually pulled up by the roots. In doing this, care should be taken to keep the root ends even. When a convenient handful is gathered, hold it loosely in both hands and let the but-ends drop on the ground several times, until they are uniform. It may now be set up in rows with the heads inclining together, as shown in Fig. 1, or bound loosely in small bundles, 3 or 4 inches in diameter, and gathered into circular shocks of six or eight bundles, with the but-ends of each well spread out, that they may dry readily.

FIG. 1.

The latter method is preferable, as the stalks are not so easily blown down. The cost of pulling is usually from five to eight dollars per acre. The straw is left standing in the field six or eight days, or until the natural moisture is dried out and the seed bolls are ripe enough to open easily. Should a storm occur, the flax may need attention to keep the bundles upright, that they may dry out quickly. When sufficiently cured, the bundles are taken to the barn or stacked in the field. In the latter case, they should be carefully arranged to exclude water. The next process is to separate the seed from the stalk, for which several methods are in use. Some use a large close-toothed iron comb, called a ripple, through

which the flax heads are drawn, a handful at a time, and the capsules torn off. Others thresh the heads with a large mallet having a curved handle. One experienced flax raiser recommends to whip out the seed by striking each bundle upon a solid block. Where the

FIG. 2.—Scale of $\frac{1}{4}$ -inch to the foot.

seed alone is desired, the practice is to thresh with a flail, or by treading with horses. The most expeditious method we have seen, is by passing the seed ends through rollers driven by horse power. A machine for the purpose is shown in Fig. 2. The rollers are set so as to break the bolls without injuring the seed; they are moved by means of a belt over the wheel, in the space between the two sets of rollers. The flax is taken in both hands, and the seed ends passed down between the rollers. Such an apparatus would pay where much flax is raised. A dry day should be chosen for taking out the seed, as the bolls break much more easily than when they have absorbed much moisture. In our next article, directions for rotting, and other suggestions will be given.

Timber Belts on Prairies.

Persons living in regions destitute of forests, find it necessary to plant trees, not only to shelter their houses from the furious winds, but also to protect their orchards and crops. While in many new countries, the energies of the farmer are directed to clearing the land of trees, the total absence of these is severely felt by those who have settled on prairie lands. In planting trees in these localities, those varieties should be chosen which are not only of rapid growth, and will soon afford shelter, but also those which are at the same time valuable for timber and for fuel.

The Black Walnut, the Maples, and Locust, are suited for this purpose. The Locust has the disadvantage of being subject to the attacks of the borer, and the limbs are sometimes broken by the winds, but the rapidity of its growth, and the great value of its timber for fence posts and the like, render it desirable to have the plantation contain a portion of these. The chestnut is another valuable tree, both for its timber and fruit. Recently, attention has been called to the White willow, claimed to have qualities which adapt it to this purpose.—As a matter of economy it is better to start most trees from the seed. Nuts, if to be transported for a great distance, should be kept in sand or loam. Walnuts are said to do better if planted where the trees are wanted, being somewhat checked by transplanting. Locust seeds should be planted in the Fall, or kept in boxes of earth through the Winter. The seeds of the maple may be kept until Spring. Plants are usually left two years in the seed bed before transplanting, keeping them free from weeds. In planting, it should be borne in mind that the object is to form a belt of timber and not a hedge; that a tree which has had plenty of room to develop its limbs will answer much better for shelter than one which has its trunk drawn up and has few limbs, from being crowded by others. The distance apart will depend upon the kind of tree—ten feet being little enough for the smallest. There should be at least two rows, and where practicable,

three or four will be better, as the trees will protect one another. By alternating the trees in the rows—that is, putting those in the second row opposite the intervals of the first row, a much more effective barrier is produced than when the trees of the different rows are placed opposite to each other. Our reasons for recommending planting the trees wide apart at once, in preference to thick planting to be afterwards thinned, are: that the growth will be better, and that where a dense grove is thinned, the remaining trees will be badly shaped and weak. Besides, in cutting away a thick plantation, the roots left in the ground decay, and are liable to injure those of the living trees. Where rabbits and mice are troublesome, the young trees must be protected from their attacks. Besides the methods we have already noticed at different times, it has been recommended to surround the trunk of the tree with pieces of corn stalk placed perpendicularly and bound closely around the trunk, as protection against mice.

Improved Wagon "Jack" or Hoister—
Home-made, Convenient, and Cheap.

I. T. Mapes, of Howells, Orange Co., N. Y., sends us a model of a wagon "Jack," or hoister as he terms it, which appears to be very valuable, from the fact that it is simple in its operation, and can be readily and quickly made by any farmer having an axe, auger, saw, and chisel. Mr. Mapes says he knows of only two having been made, and he claims to be the inventor, but he cheerfully gives the plan for the benefit of those who take the *American Agriculturist*. We take the liberty in their name to return a vote of thanks—and a large vote it is.

DESCRIPTION.—The engraving will nearly explain the construction. The base, *a*, is of 2-inch plank, say 1½ feet long and 8 or 10 inches wide. The upright, *u*, is of 2-inch plank, 4 inches wide at the bottom, and 2½ to 3 feet high, having a mortise or slot, 1½ inches wide, about half way down its middle. The lever, *l*, is cut from 1½ inch plank, and is say 3 feet long, 3 inches wide at one end and tapering to a convenient handle at the other end. This is fastened into the upright by a pin placed at the proper height from the ground to suit the wagon—about 2 feet high for an ordinary farm wagon. On the short arm of the lever a notch is cut to hold the axle. The catch, *c*, is also of a short piece of plank 14 to 17 inches long, cut to a shoulder to fit into the slot at the top of the upright, where it is held by a pin. This swings loosely and falls into notches in the lever as shown in the engraving. By depressing the lever at *l*, the wagon axle is raised and the catch, *c*, holds it there.—To the above description, which is substantially that given by Mr. Mapes, we will add a suggestion, viz.; that where

there are several wagons of different heights, the Jack may be adapted to all of them, by having the pins put in loosely, and several holes in the upright, both for the lever and the catch, so that they can be adjusted to any desired height.

For the American Agriculturist.

A Pennsylvania Corn Marker.

I believe the plan in vogue among the Pennsylvania farmers in this locality, for marking corn land, is preferable to Iowa or New-Jersey corn markers; the mark made by either of those is too narrow for planting corn in hills. A mark made by a two inch block or runner in mellow ground will "cave in," so as to leave a triangular hollow, which would receive all the grains in a heap; besides, a horse can not be made to "toe" a slight mark, or walk as straight as a human being. My experience in planting corn in hills is, that four or five grains dropped on a surface of 4 inches, do better than if thrown on an inch square. My plan is to furrow one way with a light plow; a smart man and horse can mark from eight to 10 acres per day. For cross marking, I take a light stiff pole about 23 feet long; to this I attach 6 long trace chains, (other light chains will answer) 3 ft. 5 inches apart, the first chain about 2 feet from the far end of the pole, which leaves about 4 feet of pole at the near end; on this end I make a mark 3 ft. 5 inches from the last chain. Two persons, one at each end of the pole, walk over the field cross-wise of the furrows, drawing the chains behind. The one acting as leader in marking, will walk in the last mark, keeping the mark on the pole opposite the middle of his body: by this means the two can mark twelve acres in an hour. If the first mark is straight, and the leader "minds his eye," every mark will be as straight as a line, and as uniform in width as the chains on the pole. To use this marker to advantage, the field should be in good planting order, and not be very hilly, nor too full of trees; stumps will not interfere. A common trace chain makes mark enough to be readily seen, and does not draw loose earth in the furrow to interfere with planting. The planting is done across the furrow, or with the chain mark. This simple contrivance has saved us many a hard day's travel after the plow; as we, like the Iowa farmer, were formerly in the habit of marking both ways with a plow.

Stark Co., Ohio.

JACOB HOLL.

The White Willow Again.

Western readers of the *Agriculturist* continue to write to us for advice concerning the White Willow. We have no practical knowledge upon the subject, and can only speak of the present excitement from what we see in the western papers and learn from our correspondents. That the tree will grow readily and rapidly we have no doubt. That it will, in every situation, do all that is claimed for it, is yet to be proved. We do not advise any one to invest largely in the stock, nor to expend time and money in fencing their farms with it. If the willow is valuable now, it will be as good a year or two hence. The present excitement seems to be wholly uncalled for; thousands will inconsiderately rush into it and finding that the plant does not come fully up to their expectations, the really good qualities it has, will be overlooked, and the whole affair denounced as a humbug. To those who are disposed to make the experiment we say; be sure that you get the white wil-

low. Peddlers are traversing the Western States in all directions; they may sell the true sort and they may not. It is much better to buy of responsible nurserymen. Plant a few for experiment, and if these succeed, and grow half as rapidly as it is claimed they do, they will give an abundant supply of cuttings for future plantings. In this, as all other new notions, approach cautiously, without prejudice against the truth there may be in it, and without blindly swallowing all that interested parties may say in favor of it. For ourselves, we really hope that there may be found in the White Willow just the qualities needed in a tree for the naked plains of the West, and when we are convinced that it is the thing we have been looking for, we shall gladly recommend it. But with all the light we can gather so far, we are constrained to offer a word of caution to our readers. (P. S.—Since the above was put in type, we have had a conversation with a distinguished agriculturist from Illinois, who considers the whole willow excitement as approaching nearly to a humbug. He says he has good reason to believe that an editor of an agricultural paper, which has perhaps done more than any other to push forward the willow culture, by editorials and advertisements, is himself indirectly interested in the sale of cuttings, and is thus grinding his own axe.)

A Cabbage Puller.

"Sucker," in a communication full of suggestions, describes a very simple contrivance for pulling cabbages, which would doubtless greatly lighten the labor of taking up the crop. The engraving will readily show the way in which the tool is made. The handle is 6 feet long, of 3x4 scantling. Two boards 3 feet long are nailed on opposite sides and project 18 inches beyond the end; these are rounded off like the runners of a sled. In the engraving only a part of the handle is shown, to save room. To use the implement the runners are pushed under the cabbage until the lower end of the handle comes against the stem, then by raising the other end the cabbage is easily lifted.

Dairy Statistics

Hon. Zadoc Pratt has given us the statistics of his dairy farm for 1862. He keeps 64 cows, which for the season of about eight months produced 35,740 gallons of milk, or an average of 2 14-100th gallons per day for each cow. The whole product of butter was 14,274 lbs., equal to an average product for each cow of about 13½ ounces per day. Each cow yielded butter to the value of \$57.98. The following table shows the amount of milk required to make a pound of butter on the first of each of several months for three years; and also the weight per gallon of the milk at the time.

Blooded Stock—Present and Prospective Prices, etc.

If, from want of information or from prejudice, any one still doubts the value of *improved blood* in stock of any kind, over that of the "old-fashioned" or "native breeds," the simple market quotations of the cattle, sheep, and swine sales in New-York City, for the last two years, will show him the difference. We set aside all the *ornamental* appearance of the quadrupeds—which, by the way, any one with an eye in his head, or a soul in his body, would count as worth something—and only take into account the simple *economical* value of well bred over ill bred animals. We do not propose to enter into particulars, even. Just go up to the Bull's Head on cattle-sale days, and see the quick, liberal prices *paid* for beeves, high up in Short-horn, Devon, or Hereford blood, and then the slow, lagging, liggling prices for which the "dung-hills," "scallawags," and common stock are *offered*, in many instances without buyers. And yet, with the breeder, the grazier, and the feeder, both descriptions of beasts have run side by side in the pasture and feed yard. One, from its nicely and skillfully adjusted anatomy, has the faculty of taking on flesh readily, kindly, and in the most valuable parts for good quality of meat; the other, from its ill-adjusted anatomy, has not such faculty. And the better beast has, in all probability, eaten less food, while taking on a third more flesh than the poorer one.

So with sheep as with cattle; the same also with swine—poultry even. The war, with its deranging influences on sundry of our economical products, has reduced the values of purely bred stock to almost nominal prices, and hundreds, perhaps thousands, of young thoroughbred bulls have been made into steers for the shambles, instead of being purchased and distributed over the country for stock purposes; and multitudes of equally well-bred South-down and Cotswold rams, as wethers, have shared a like fate. So, too, with young boars, while the spaying knife has been busy among the breeding sows—all turned off for market purposes, and food consumption.

We Americans are a wonderfully spasmodic people in thought and action. Nearly thirty years ago we imported Short-horns from England, and sold them at a thousand dollars each for breeding and improving purposes. Ten years afterward, descendants of the same stock, equally well bred, could be bought for a hundred dollars each, or less. And so it went on for ten years more. Beef had risen in our sea-board markets. Then came another furor. Our native-bred Short-horns and Devons could not supply the demand, and by careless breeding, at low prices, their quality had in many instances deteriorated. Hence new English importations, and a furor of demand far exceeding any previous rates in price. A freshly imported bull sold in Kentucky for \$6,000, and he never got a calf! Sundry other bulls sold for \$2,000, to \$3,000, and sometimes more; and cows from \$1,000 to \$2,000 each! And now, just as good animals sell for \$100 to \$300 each, while the New-York market price for beef has not fallen more than 20 per cent. over the highest prices, in first quality cattle! Yet the better ones pay well at their present selling prices, and the "scrubs" scarcely pay for rearing, feeding, and getting to market. The same comparative story may be told of sheep and swine. Two years ago wool was a drug, and sheep hardly worth

the asking. Wool was worth 20 to 25 cents a pound, for common quality, and the finest scarcely 40 cents. Now, one can scarcely ask a high price enough for sheep, for all the world wants them; and common wool is worth just as much as any other, and sixty cents a pound! Every body is after sheep, and putting away cattle. Yet, dairy products—butter and cheese—are high, and milch cows worth something.

We have no advice to give, but having told a few facts, sensible men can draw their own conclusions. If we had fine stock of any description, we should cherish it. We would keep every good breeding female, and make *steer*, or *wether*, or *shoat*, only of such males as we could not sell; for there is a time coming, and at no distant day, when blood stock will be in demand.

Black Rock, Erie Co., N.Y.

L. F. ALLEN.

Hints on Feeding Horses.

The following extract from a valuable practical address delivered by an *Agriculturist* subscriber in England, (G. P. H. Paty, M. A.) before the Farmers' Club at Bideford, Devonshire, contains hints on winter-feeding of horses equally applicable to this country. It will be remembered that *corn*, in England, signifies grain of any kind; and *chaff*, means cut hay or straw:

"Hay and oats will always form the staple of horse food here, but variety is without doubt as pleasing to the horse as to man, and there is little trouble in varying the regular diet occasionally. Hay, whether meadow or clover, and oats and beans should possess the same good qualities. They should be bright in color, sweet in smell, and free from any mustiness, and should not be used in the same year in which they are grown. A good many of the oats brought into this market will be found to weigh less than 36 pounds a bushel. I have grown the black American oat to weigh 40 pounds a bushel, and the white Canadian oat to weigh nearly 46 pounds a bushel, and as comparative weight in grain is a decisive test of quality, the superiority of this class of oats is obvious. Good food will be found the cheapest, and those who use inferior fodder under a delusive idea of economy, will find that they only gain a loss by doing so. Beans may be considered the chief horse-corn next to oats, and when bought at a reasonable price, and given to the horses with a recollection that one feed of beans may be considered nearly equal to two feeds of oats, will be found a useful change. That mixture of barley and oats known here as dredge, is also often used for horses, but I have not used it myself, from an opinion that oats and beans are preferable. Oil cake in small quantities, say two or three pounds a week, will be much liked by the horses, and I think it exercises a decidedly good effect on their coats. Turnips, carrots, of which most horses become immoderately fond, mangold wurzel when they will eat it, trifolium incarnatum, and early vetches, will afford a sufficient range to enable the food of the horse to be varied from time to time. The question of crushing corn for horses is constantly brought before us by advertisements. Its necessity, for young horses at least, is to me doubtful; and the evidence of the stock authority on the subject, as quoted in the advertisements—a London Omnibus Company—is entirely vitiated by the fact that in the experiment in question, crushed corn and chaff were used against whole corn and hay, thus only proving the general advantage of comminuted food, and not the special advantage of crushed corn. By feeding horses regularly,

and mixing chaff always with the corn, I think you will ensure its being properly ground, without the intervention of any other mill than that provided by nature. When the chaff and corn are given to the horses, enough water should always be sprinkled over the feed to moisten it, and lessen the horse's desire to drain the bucket to the bottom. I am strongly in favor of the use of chaff for horses, but I would recommend any one who uses it to discard all idea of cutting it by hand, and to arrange for the use of either water or horse-power, according to circumstances. Fifteen pounds of chaff a day, in the proportion of ten of hay and five of straw, with a peck, say nine or ten pounds, of good oats, 12 pounds of carrots, and a small allowance of hay at night, will form good winter feeding for a horse in full work; but the quantity, of course, must be suited to each horse's wants, remembering always that a horse that is regularly well fed will require less and do better than a horse that is stinted at one time and over-fed another."

"Scratches" in Horses.

This disease, called also "grease" in England and in some parts of this country, often attacks the heels and legs of neglected horses, and though easily prevented, is difficult to cure, if of long standing. It commences with inflammation of the oil glands of the skin about the hind feet. These vessels, named *sebaceous* glands, supply a fluid to soften the skin and prevent its cracking. These glands are especially needed and very active about the hind feet of the horse, where, by frequent exercise of the parts, the skin is subject to almost constant alternate wrinkling and expansion. The toughest leather would soon yield under such treatment, unless kept well softened by oiling. The oil glands may become inflamed by sudden cold, as when a horse after exercise over wet roads is allowed to stand in the stable without cleaning and drying the hair about the feet. The animal being warm, moisture rapidly evaporates and carries with it the heat from the neighboring parts; congestion ensues, and inflammation commences. It may be slight at first, but by neglect it will be likely to extend and affect the surrounding surface and also the deeper seated structures, resulting in a disorder disgusting in its appearance, and painful to the horse. Or it may be caused by standing on a filthy stable floor in wet straw and excrements, the moisture from which not only produces cold, but from its nature irritates the skin, thereby inducing the disease.

As it progresses, the hair drops off, the heels swell, the skin assumes a glazed appearance, is covered with pustules, and emits an unctuous discharge which soon becomes very offensive. Unless properly treated, the leg half-way to the hock is crusted over with thick, horny scabs, divided by deep cracks, when the affection is scarcely curable. Prevention is found in clean stables, and in thorough drying and rubbing of the legs after the horse has been used. Close clipping of the hair which ordinarily grows long about the legs, deprives these parts of their natural protection, rendering them more liable to the scratches, and is therefore objectionable.

If the disease unfortunately appears, Herbert recommends to clip off all the hair from the affected parts, and thoroughly cleanse them with warm water and Castile soap. Then apply a flannel bandage evenly over the limb, and frequently moisten it with warm water, allowing it to dry on the part. To soften the skin, apply an ointment of one drachm of sugar of lead in an

ounce of lard. If there are cracks, wash them with a solution of four ounces of alum in a pint of water. Feed the horse on bran mashes, carrots, and green feed, and if there be much inflammation after a day or two, administer a ball of four or five drachms of aloes.

If the disease has reached the second stage, three doses of physic at intervals of two days will be needed. The best application to the heels will be a poultice made of boiled and mashed carrots, put on tolerably hot. It can be conveniently applied by drawing an old stocking leg over the leg, confining it at the fetlock joint, and filling it from above with the poultice. When this is removed, anoint the heels with an ointment of one part of rosin, three parts of lard melted together, and one part of calamine powder, added when the first mixture is cooling.

For the American Agriculturist.

Notes on Sheep-Raising in Ohio.

The late census report places Ohio at the head of the list in sheep husbandry. To a genuine Buckeye, one having a becoming pride in the prosperity of that place which is his home by birth or adoption, this fact can not be otherwise than gratifying. In 1850 the whole product of wool in the United States was about 52,000,000 lbs. In 1860 the clip increased to sixty and a half millions of pounds, showing a gain of over 15 per cent. during this period. Of this, Ohio, in 1860, produced 10,648,000 lbs., and although we have decreased over 800,000 in the number of our sheep since 1850, yet we have increased over 400,000 in pounds shorn. This increase of wool from a less number of sheep, clearly indicates a more intelligent system of breeding, and better management of flocks. Ohio has near 10,000,000 acres of land under improvement, and only a fraction over 3,000,000 sheep—less than one sheep for every three acres of cleared land—it is therefore obvious that the number may be greatly augmented without being over stocked, or materially affecting other important agricultural interests. That sheep husbandry is now assuming a more important position in the economy of the farm than heretofore, is evidenced by the demand and prices paid for sheep at the present time. During the last year, wool has advanced about 50 per cent., while sheep have advanced fully 100 per cent. New men are now attracted by the price of wool to embark in the business of wool growing, and almost every farmer is increasing the number formerly kept on his farm. This, I by no means condemn, and yet it may not be out of place to offer a word of caution. The wisest man can not predict what is before us, or what will be the condition of our Nation one year hence. I do not despair, and I yet hope my country and Government will be saved, but, in our present distracted condition, I would certainly hesitate before embarking in any enterprise involving a large investment. And furthermore, is not the present price of wool delusive? I grant that in making the currency of the country the standard of value, wool has advanced 50 per cent., but if I desire to convert this currency into gold, or if I only accept gold in payment for my wool, I will then find the last year's prices closely represent its absolute, or true value at the present time. But while I would advise caution, I would also applaud every wise and well directed effort to increase the number, and still further aim to advance the present high character of our Ohio flocks.

If a good Providence grants power to our

Government to subdue, and crush this wicked conspiracy against its life, then surely the flock-master may look forward for some years to come, with assurance that his labors and care for his fleecy charge will be well rewarded. The present supply of wool in the markets of the world is unusually small, and cotton both from scarcity and price, can not as heretofore constitute so prominent an element in our professedly woolen fabrics. G.

Moore's Salt Works, Ohio.

A Word for Merino Sheep.

Mr. M. Cunningham, Stark Co., O., in answer to the question proposed by the Ohio State Board of Agriculture, "Which are the Best Sheep?" writes as follows: "This question may have as many different answers as men have different notions and opinions. To the flock-master, who breeds and keeps sheep for the wool principally, the Spanish Merino is esteemed above any other, in this climate. Some of the reasons for this are as follows: The Spanish Merino produces a greater quantity of wool, in proportion to the size of the carcass, than any other variety of sheep. It is a generally admitted fact, that all animals consume food in proportion to the weight of carcass. This being the case, and the difference in weight between a Spanish Merino and a Leicestershire or a South Down, being about one-third, it will readily be seen which of the two varieties is most profitable for wool; for, generally, it will be found that the well-built, close and compact Spanish sheep of eighty pounds weight will produce more pounds of wool than the Leicestershire or the South Downs of one hundred and twenty pounds. If this be true, it requires one-third more feed to produce a pound of wool from a Leicestershire or South Down sheep than it does from a Spanish Merino; while, at the same time, a pound of the Spanish Merino is worth and will sell for at least one-third more than the other. [Generally—but not now. Ed.]

The wool of the Spanish Merino is generally very compact and close, and being oily also, it protects the bodies of the animals from the inclemencies of the weather; while on the loose, open, and light woolled varieties, when exposed to the rains and storm, the wool becomes saturated, the water finds its way to the skin, the animal takes cold, and perhaps dies.

Spanish or some other of the Merinos, herd together in large flocks better than Leicestershire, Cotswolds or South Downs. They are, perhaps, the most quiet and docile variety of sheep of all others. This is a great consideration."

Introduction of Merinos.

The Northampton (Mass.) Free Press, claims for Vermont the honor of having first introduced the Spanish Merino into the United States, and gives the following account of the importation: "William Jarvis, a native of Boston, received from Jefferson an appointment as Consul to Lisbon, and when there in 1811, Napoleon invaded Portugal and Spain, and some of the flocks were seized by him to feed his army, while others were sold to defray the expenses of the war. Previously, not a single sheep had been allowed to leave Spain, the penalty of death having been established to prevent it. Mr. Jarvis wishing to benefit his countrymen, purchased ten bucks at a cost of \$200 each, and shipped them to New-York. He ordered his agent to advertise them thoroughly and then sell them at auction. His

request was complied with and the report of the sale was sent to Mr. Jarvis. He opened the letter, from which he read that his sheep had been sold at \$100 each. The letter was thrown down in a passion—and his countrymen were considered the most unappreciative people in the world. He thought they certainly might have shown gratitude enough by paying at least what the sheep had cost him. The next day having occasion to refer to the letter, he found that he had made a mistake of one cipher in the first reading. Instead of the sheep having sold for \$100 each, they had sold for \$1000—a slight difference. This induced him to make further purchases, and during his stay at Lisbon he shipped to this country 3,500 sheep, all but 300 of which were sold at New-York, Boston, Portland, New-Haven, and Philadelphia at enormous prices. The 300 that he reserved, were taken to Wethersfield, Vt., where 8000 acres of land had been purchased at a cost of \$20,000. On his return to this country, Mr. Jarvis settled in Vermont, and continued the rearing of sheep, from which, together with the profits made on those that he had imported, he had amassed a fortune."

It is true that Mr. Jarvis was the *largest* early importer of this breed, but S. S. Randall in his work on sheep states that the *first* Merino received here was shipped by Mr. Delessert, a banker of Paris, in the year 1801. Four animals were sent, but three died on the passage; the remaining one was taken to a farm near Kingston, in this State. In 1802, Chancellor Robert R. Livingston, of New-York, imported two pairs of this breed, and in the same year Hon. David Humphreys, of Connecticut, imported a flock of about one hundred.

Economy in Wintering Pigs.

A correspondent at Sandy Hill, N. Y., sends to the *American Agriculturist* a description of his mode of wintering pigs economically—in substance as follows: The pen is built adjoining the rear of the horse stable, so that the pigs can have free access to the manure heap. Their grain feed is thrown upon the pile to encourage them to work it over, and also that their own excrements may be dropped there. The trough for swill is placed outside of their nesting apartment, midway between that and the manure heap. The whole is under cover, and seldom freezes. Pigs for wintering are taken from the second litter, dropped in September. Two or three pigs are kept to each horse. They spend most of the day in working over the manure thrown from the stable in the morning: thus all the undigested grain, which would otherwise be partially wasted, is turned to account; an addition is made to the manure heap by the pigs, and the whole is thoroughly commingled. It is claimed that a large saving of feed and manure is made. Toward Spring the manure is thrown out of the pen, and allowed to ferment. The heap is watered occasionally, if it be not sufficiently moist, to prevent fire-fanging.

We suggest in addition to the above plan, that a pile of muck be kept near at hand, under cover, and a few shovelfuls be thrown in daily with the manure from the stable. It will retain much of the ammonia which would otherwise escape, thus preventing the offensive effluvia from the sty. It will add largely to the bulk of the heap, and by being incorporated with the manure, prevent injury during fermentation. Sods, or any good soil may be used, when muck is not at hand. The accumulation can be removed from the pen as often as necessary.

The Petunia—New Varieties.

The improvement which has been made in this favorite bedding plant is truly wonderful, when we compare the present forms with the old white and purple kinds. The engraving here given, represents some of the seedlings produced by Mr. Isaac Buchanan, the well-known florist of this city. Being dissatisfied with the double varieties, he turned his attention to those with blotches and markings. Beginning with a blotched plant which he brought from Gand, he has, after several years of careful culture, succeeded in obtaining some well marked varieties—the beauty of which is reproduced in the engraving as well as can be done in black and white. In the specimens we have seen, the markings are well defined, of a rich purple color, on a clear, white ground. We cultivated some of these varieties last Summer, and their striking contrasts of color made them the most brilliant ornaments of our grounds. The petunia, from the ease with which it is propagated, is exceedingly popular. Though a perennial, it is cultivated like an annual, and blooms very early from seed sown in the open ground. Towards the end of summer cuttings may be made from desirable sorts. These strike readily, and may be kept for winter blooming, or in a dormant state for spring planting. A paper of seeds of the finer sorts will be likely to give a considerable variety of colors and markings.

For the American Agriculturist.

Impositions in Grapes and Other Fruits.

These are continually occurring. Here are a few from which I have personally suffered. Several years ago, following the advice of influential persons, I purchased a rooted layer of the *Logan* grape. It was said to be equal to the *Isabella*, but hardier, more productive, and ripening before the *Concord*. Even more than this was said in its praise, but this was enough, if true. So I remitted the \$5 demanded, and received a vine. It has now borne fruit three years, and I must testify that it is *not* equal in quality to the *Isabella*, and not half as productive as that variety. It is early and hardy as could be desired, but it does not set its fruit

well; in this regard it is inferior to the *Concord*. More recently I bought a *Cuyahoga* vine, for \$3; a "knitting-needle" vine, too. The first plant died, and next year I tried again, with another needle, which lived. The recommendations of this grape were very high. Here is

small village near Plattsburgh, N. Y. A recent correspondent of Hovey's Magazine writes from that village, saying: "The original *Adirondac* vine stands but a few steps from the lake, in the town of Port Henry. I do not think it equal to the *Delaware*, *Diana*, or even *Concord*, for this

region." That is certainly quite a *home thrust*. The writer charges no one with dishonesty, but counsels the public to be extremely cautious not to pay large prices for *untested* novelties of any kind. VITIS.

REMARKS. — We can scarcely wonder at the state of mind, in which "Vitis" finds himself; he has not a few sympathizers. The gist of his letter is contained in one of the last words, which we have italicized. It is not enough that one interested person, with the experience of one locality, shall recommend a grape as the best ever grown, though he may intend to speak ever so honestly. Our enterprising propagators are always on the lookout, and ready to spend money and time in testing all promising novelties, and many of them are honest enough to speak and act upon the facts regarding a new vine. Some are unscrupulous enough to help keep up the factitious merits of any new plant, until the public have repaid to *them* their outlay in the experiments; but there are enough of the former class to soon put a plant upon its proper level of merit. For the masses it is generally safe to wait for the testimony of leading propagators in favor of a

PETUNIA.

one, published in the Horticulturist: "Ripens ten days or two weeks earlier than *Isabella*, is free from rot or mildew, ripens its berries uniformly, and they hang well on the bunch. Pulp melting, juicy, sweet—quality best." But last year the facts began to leak out. Reports of its rotting and mildewing found their way into the papers. The specimens exhibited at the different fairs were few, small, and poorly ripened, and, worse than all, they were found to be *later* in maturing than the *Isabella*. That, of itself, kills it for cultivation in a northern latitude.

The *Adirondac* grape has lately come out with a brave blowing of trumpets. This is declared to be certainly superior to the *Isabella*, has a touch of the flavor of that royal grape, the *Black Hamburg*, is very prolific, hardy, ripens before the *Concord*, etc., etc. This sounds well, but I am getting nervously shy of these untried novelties. The *Adirondac* originated in a

grape or other fruit, before investing in it. A little time may be lost in securing a variety that proves to be valuable, but the security against imposition will make up the loss. Men of wealth, those who can afford to lose the outlay, may well experiment with every thing new coming up, whenever there are any reasonable grounds to hope for good results. By so doing, they confer a benefit upon the public.—ED.]

Downing's Everbearing Mulberry.

This variety of mulberry has now become pretty widely disseminated, but of its real merits very little is yet known, except by the few who have eaten the fruit from trees six to ten years old; that from younger trees being always inferior to what is grown on those that are old and mature. Several other sorts very much

resemble the Downing, but do not have that sprightliness of flavor which makes this variety so desirable. The fruit is about an inch and-a-half long, half an inch in diameter, and black when fully ripe. The tree is hardy, very vigorous, a rapid grower, and is also ornamental; leaves, very large, heart-shaped, often ten inches long and seven broad. It is said to be a seedling of the *Morus Multicaulis*, which it very much resembles in foliage, but it has not the peculiarity of the *multicaulis*, of growing readily from cuttings. We are not aware of any one having succeeded in growing it in any quantity in that manner. The most successful method has been to graft it on roots of other varieties, performing the operation in the months of March and April, under glass. In this manner every graft can be made to grow, and as soon as they have become firmly united to the stock, they may be planted out into the open ground. The planting should always be deferred until all danger of frost is past. It may also be grafted or budded upon stocks in the open ground, at the usual time for budding and grafting other trees. We know several instances where this has been practised with moderate success. The fruit begins to ripen in this vicinity by the middle of June, and continues without intermission until the middle of August, thus filling up the space between the strawberry and grape. It is too soft for market purposes, and has one other serious fault, viz.: the stem of the fruit adheres to it so firmly that it must be either cut off or eaten with the berry, as it can not be pulled off without breaking the pulp.

Severe Treatment for Peach Trees.

A correspondent, Samuel Godshall, of Hubbard, O., seeing hot water noticed as a remedy for diseased peach trees, in the *Agriculturist* for January, sends an account of his experience which, like the others, is published for those who wish to make an experiment. It strikes us as rather a severe remedy. If the heat did not kill the tree it would be quite sure to destroy the grubs. It may be that the killing of the grubs is due to the potash contained in the ashes, and that cold ashes would be as efficacious. At any rate the potash contained in the ashes would be useful as a manure to the tree. "Some years ago, I had a large peach tree standing in the corner of my garden. When it put out in the spring the leaves were yellow, knotty, and curled; every thing indicated that the tree must die. When digging that part of my garden, I concluded I would try an experiment on the old tree. I took my shovel and bared the roots for more than a foot round the body of the tree. I then carried three large shovelfuls of hot hickory coals and ashes, threw them on the roots, and immediately covered them up with the fresh dirt. I noticed immediately a great steam rising from the roots. In a few days the tree cast off its leaves, and put out afresh, and before harvest it was covered with a dark green foliage, and year after year while I lived on that property, that old tree was the admiration of all who saw it, both in fruit and foliage. Since that time my cure for the peach tree is hot coals and ashes, and I have always found it a success. I have on my lot at this time a small orchard of perhaps as healthy peach trees as can be found in the State of Ohio. And my mode of treating young trees is, in the Spring to examine the roots, and if I see signs of grub, to apply the hot ashes immediately, and through the season apply night soil."

The Great California Pear.

This pomological monster, the anticipated arrival of which was announced in the February *American Agriculturist*, came safely to hand—thanks to the careful packing of Col. Warren, and the courtesy of Wells, Fargo & Co. It was placed on our Exhibition Tables, and was examined by many thousands, and we have had it engraved for the benefit of other tens of thousands who were not able to see the original. The engraving is of the exact size, and gives a very faithful representation of the pear. It is 20 inches in circumference one way, 16 the other, and weighed here 3 lbs. 7 ozs. A model in wax, colored by Dr. Newberry, so truth-

fully that many were in doubt which was the original—is still on exhibition. No information as to the variety of the pear, accompanied it. A committee of the Fruit Growers' meeting was appointed to test it, Jan. 29, but decay had progressed so far that they were unable to form a satisfactory opinion. It was thought by some of the committee that, notwithstanding the dissimilarity of form, it was a monstrous specimen of the old Pound Pear. Whatever it may be, it has certainly been very interesting to amateurs in fruits, and others, and our thanks are due to Dr. Bellows, to whom it was sent by Thomas Brown, Esq., and to all who participated in enabling us to show what the wonderful soil and climate of California can produce in the way of

pears. We have heard of larger pears, but this excels in weight and size any other one that we have ever seen. It weighed full *three pounds and seven ounces* after its arrival here.—P. S. Since writing the above, a gentleman whose name we did not learn, called and informed us that he was a neighbor of Dr. Beard at the San Jose Mission, and that he was knowing to the fact that the tree was taken to California six or seven years ago, from the nurseries of Messrs. Parsons & Co., of Flushing, N. Y. Both himself and Dr. Beard ordered a considerable number of trees at the same time, among which was the one producing the above specimen, as well as its predecessor, the "Bushnell Pear."

Dwarf Apples.

To any of our readers who may be discouraged with dwarf pears, we would recommend a trial of dwarf apples. They are produced by grafting the ordinary apples on the Paradise, or Doucin stock. And here lies an advantage or two; one does not have to wait and carefully experiment, as with pears, to find out what kinds will succeed as dwarfs, what need double-working, etc. Take any sort desired, and, if properly grafted, it will succeed, and be fruitful much earlier than the common apple tree. Those grafted on the Doucin stock will usually fruit the fourth year, and those on the Paradise the third year. Fire-blight, sap-blight, and hard winters seldom trouble the dwarf apple.

These dwarf trees are desirable for small gardens and village door-yards. Common apple-trees need to stand 20 to 30 feet apart, and of course there can be very few of them planted in ordinary town-yards, but dwarf trees may stand at eight feet apart for the Doucin and six for the Paradise. This will enable a family to raise quite a pretty assortment of dessert apples. Of those which naturally form roundish, symmetrical heads, we note the Red Astrachan, Porter, Baldwin, Dyer, Summer Rose, and Sweet Bough. The following, though a little rampant and irregular, yield fine fruit: Lady Apple, Early Strawberry, Wagener, Northern Spy and Tompkins' King. As a general rule, summer and autumn fruits should be raised on the dwarf stock, and the orchard depended on for the general winter supply.

Hints in Pruning.

Pruning is not an indiscriminate cutting, but is an operation to be performed according to certain rules. The cut should always be made near a bud. If the cut is made for some distance above the bud, the wood will die down to it. Hard wooded trees should be cut as shown in fig. 1. The cut commencing opposite the base

Fig. 1.

Fig. 2.

Fig. 3.

of the bud and sloping up to a point opposite to the top of it, as shown by the dotted lines. In fig. 2, the cut is too far above the bud, and a stub is left which seldom heals over, but rots. In fig. 3, the cut is made too near the bud, with too great a slope, and there is danger of its dying.

Recollect that the bud will form the future branch, and the shape of the tree will be governed by the choice of the bud left to continue the growth. Soft wooded trees and shrubs should not be cut quite so close to the bud as those having hard wood.

Dwarf Pears.

J. Franklin Spaulding, of Nashua, N. H., thinks that the pear throws out roots only on strong loamy soils, unsuited to the growth of the quince. He removed some dwarf pear trees which had been planted for 23 years, and found the quince stocks all in healthy condition. These trees had all been set with the juncture of the pear and quince about 6 inches below the surface. His experience is, that upon soils suited to the quince, the stock will last as long as the pear. He doubts if the pear will throw out roots where the soil is properly cultivated, unless the trees are mulched, as the soil would otherwise become too dry to favor the formation of roots.

Notes from the Fruit Growers' Meetings.

JANUARY 15.

KEEPING FRUITS.—Dr. Ward presented a plate of Lawrence pears, in good condition. This has not hitherto been regarded as a Winter variety. He allows the fruit to remain late upon the tree, which holds its foliage longer than most other pears. It is then placed in the cellar, which is ventilated by admitting air from without as often as it can be done without danger of freezing. He thinks that fruits keep much better when the exhalations arising from them are removed. The specimens had been kept in a warm room for about two weeks, and upon testing were found to be of most excellent quality. Dr. W. thought he would have no difficulty in keeping the Lawrence until the 1st of March.

Mr. Carpenter had not been so successful; all his specimens of Lawrence were gone before Jan. 1st, while the Vicar of Winkfield and Glout Moreau would keep until April. He thought the quality of the soil affected the keeping of the fruit. The subject of retarding fruits was regarded as one of great importance. It was conceded that nothing was equal to ice for this purpose.

Dr. Ward was convinced that the best and most economical method of using ice had not yet been discovered. He was making some experiments, which he hoped to lay before the meeting at another time.

Mr. Carpenter had found nothing like ice; he had, by means of it, kept the Bartlett into October, and thus realized three times the usual price, and believed that a correct method of using ice would not only be profitable to the fruit growers, but would be the means of benefiting the public by prolonging the season of choice fruits.

Mr. Fuller wished for some simple way to preserve fruits which could be practised by every farmer, and asked if fruit in closed boxes or barrels, kept better than when open. He put them in tight boxes, after sweating. It was thought that no general rule could be given, that it depended upon the peculiarity of the kinds. Pears with a thin skin, like the Flemish Beauty, should be exposed, while those with a tough skin, like the Lawrence, should be confined.

In reply to the question whether any packing material was useful, Mr. Carpenter stated that it was, for preserving a uniform temperature. He thought rice chaff was best, and next to that oat chaff. He packed his fruit in it, and left the barrels out until there was danger of freezing, and then removed them to the cellar. He found, on opening a package the day before, that the fruit was 10 or 15 degrees cooler than the atmosphere of the room in which it was kept.

GRAPES.—In the discussion upon a list of grapes to recommend for cultivation in the vicinity of New-York, several cultivators gave their experience. Mr. Oliver advocated the claims of the Concord for prolific bearing; was planting 17 acres of this variety; considered it the only native grape that would make wine without sugar, and presented samples of brandy, which were pronounced good. It took eight gallons of grape juice to make one gallon of brandy.

Dr. Ward said that the Concord stood the sun as no other grape would; had it growing by the side of other grapes, and found that the foliage remained fresh, while that of the Isabella and other grapes was curled by heat.

Mr. Fuller remarked that the wood of this variety ripened early—long before the leaves fell.

Mr. Field said we needed a substitute for the Isabella. People would go on planting that variety, because they knew of nothing better. This was a great mistake, and would only lead to disappointment. The Isabella was not adapted to exposed situations, and would only grow upon the south side of some protecting object. In city yards it did well, but in open places it was not worth planting. Knew a vineyard which had been planted seven or eight years that had never yielded a perfect cluster. He thought that the Concord was the best grape he ever knew.

Mr. Carpenter thought the Concord the grape for the million—it gave good fruit if neglected, and better if cared for. As the Delaware needs more care, he would place the Concord at the head of the list. The Hartford Prolific was very early, ripening two weeks sooner than any other, but it would not give fine fruit without extra care, and on that account was not proper to recommend; the same with the Diana. The Isabella he would condemn, for it disappointed thousands. The Iona he thought highly of, and believes it will supplant the Delaware.

Mr. Fuller objected to recommending a variety which, like the Iona, was not generally obtainable.

Dr. Trimble had seen an abundance of the fruit of the Delaware at the exhibitions in New-Jersey. Knew of 35 bunches being raised on a graft two years old.

Mr. Field thought the Delaware would improve with time. The Diana had improved with him, and made stronger wood. He thought the Delaware would beat the Diana and Isabella anywhere, in open grounds.

Mr. Saxton had 100 bunches on three vines of the Delaware, planted out only two years.

JANUARY 22.

GRAPES.—*Varieties recommended.*—After examining the great California Pear, the varieties of grapes to be recommended for general cultivation, especially in the vicinity of New-York, were discussed.

Dr. Trimble moved a resolution, which was passed, that Mr. Borland of Bucks Co., Pa., be requested to communicate his method of grape grafting to the meeting. —Mr. Cummings thought that this method of propagation might often be useful when slow growing varieties of grapes were grafted on quick growing stocks.

Dr. Ward thought we should be very cautious in coming to a conclusion about this method of propagating the grape, from a single experiment. When the grape was grafted on an old root it was a long time before a good plant could be secured. The old roots decayed before there was sufficient foliage to keep them growing.

Mr. Mead would place the Delaware at the head of the list, but it needs the high culture and care that few persons will give to it. He would then place the Concord first, and the Isabella third. He would substitute the Creveling if it could be obtained. It ripens 10 to 12 days earlier and is superior to the Isabella; but he would not discard an old variety for one which is not generally in the market. He would name as those which promise well; Creveling, Allen's Hybrid, and Cuyahoga. There are others which he considers more promising than these, but they are not before the public.

Mr. Field gave as his selection Delaware, Concord, and Hartford Prolific, and for particular localities, Diana, Catawba, and Isabella.

Mr. Fuller named Delaware, Concord, and Hartford Prolific for general culture; and for special localities, Creveling, Cuyahoga, and the Iona if it could be obtained.

Mr. Carpenter gave Concord, Delaware, and Hartford Prolific as his choice. He put the Concord first, not because it was a better grape than the Delaware, but because it will bear neglect and make its own way, ripens in good season, and will flourish as far north as any grape will. As promising well, he would name Iona, Allen's Hybrid—would add Cuyahoga but fears it ripens too late, therefore substitutes Creveling.

Mr. Cummings was surprised that no one had mentioned the Adirondac, which ripens early in a high latitude. It was answered that no one present had fruited it, and that it was not right to recommend varieties which had not been tested, or those monopolized by one seller.

Dr. Ward recommended Concord, Delaware, and Diana. The Concord would grow in any soil, will carry its fruit to perfection, has large bunches, is of fair quality for the table, and good for wine. Is already to be found in the market while, though he often visits the Washington market, he never saw a bunch of the Delaware on sale. While the Delaware would, with high culture, give a superior fruit, he preferred the Concord for these reasons. Has had experience with the Isabella, cultivated and carefully trained a vineyard of 500 vines for 10 years, and it has never paid the original cost of the vines. He was tired of it. Objects to the Hartford Prolific as, without being earlier than the Concord, it requires careful pruning.

Mr. Judd gave as a list for general culture, the Concord, Delaware and Diana. The Delaware was, from all accounts, the best flavored grape, and to be recommended. He named the Concord first in such a list, on account of

its great vigor; a root stuck in the ground carelessly, would be likely to grow with or without care, and produce an abundance of fair quality grapes. It would perhaps best meet the wishes of the great mass of careless or inexperienced cultivators. The Delaware would give the best fruit to those who would take any pains in cultivating it. The Hartford Prolific was an early grape, a vigorous grower and bearer, but these qualities were nearly equalled in the Diana, and its sweeter flavor would be relished by many; to make up a variety, therefore, he would put the Diana third in the list, instead of the Hartford Prolific.

Solon Robinson gave Delaware, Concord and Hartford Prolific as his choice.

Mr. Pardee would place the Delaware at the head of the list: thinks from what he has seen, that when the vines get older they will bear as well as the Concord. It has not had time to show what it will do. He would add Concord and Diana, and for those which promise well, Hartford Prolific, Allen's Hybrid, and Isabella. The latter is, in many localities, too fine a grape to be discarded.

Mr. Cavanagh said he had had charge of the original Isabella vine, and did not believe that one vine in ten of those known by that name, was of the true kind.

The vote on varieties for general cultivation was taken as noticed in another column.

JANUARY 29.

Discussion upon Grapes resumed. In answer to queries about the Anna, Messrs. Field and Carpenter concurred in considering it too late, but that it is not yet fully tested.

Mr. Carpenter thinks that, among White grapes, Allen's Hybrid is the most promising. It ripens with the Diana, or a little before it. A hardy white grape is very much needed. The Rebecca is a good bearer, has a fine bunch and desirable fruit, but makes a very delicate growth.

Mr. Fuller considers that all of our native white grapes are seedlings of the Isabella—are albinos, so to speak, and are of weak constitution. Allen's Hybrid has poor foliage; he thinks it is not a hybrid. Hopes it is, but doubts. A Committee was appointed to test the great California pear. Their decision will be found on page 81.

Mr. Carpenter exhibited about half a peck of Vicar of Winkfield pears, which were freely tested and showed the efficacy of his plan of preserving them in oat chaff.

Some lists were handed in by members of the Committee on Apples, which gave rise to some discussion.

In answer to the question if fruit growers near New-York had found the apple crop profitable in a year of such plenty as the last: Mr. Carpenter replied that with cider at 10 cents a gallon, it would pay even for cider making. He thought that all good and well cared for fruit had brought paying prices during the last season, and that he was encouraged to increase his orchard.

Harvey Dodge of Worcester Co., Mass., has been preparing ground for an orchard by thorough draining, at an expense of \$200 per acre. Is planting largely of the Hubbardston Nonsuch. Is trying the Northern Spy, which does well.

FEBRUARY 5.

Mr. Baldwin, of Hanover Neck, N. J., exhibited Peek's Pleasant apples of great beauty and fine size. Considers the tree a great bearer, and knows of nothing better. They sold readily this winter at \$1 a bushel.

The Diana grape was discussed. Mr. Fuller does not fancy it much, as it ripens poorly, and of uneven size; considers it an improvement on the Catawba.

Mr. Judd planted Dianias in 1856, and finds them to be strong growers and prolific, and prefers it to the Concord.

Mr. Wood stated that at Croton Point, it does not ripen every year, but when well ripened, it is superior to the Delaware. Placed on the list for special localities.

The Isabella next came up for consideration, but the remarks upon it were of a similar character to those already given above.

Large Returns from Small Outlay.

A correspondent, Joshua Thornby, of Greenfield, Mass., wishes us to call attention to a profitable kind of gardening which he has followed for some time—that of raising early plants for sale. He thinks that, from his experience, one subscriber of the *Agriculturist* in every village in the country, can realize a handsome sum by raising plants and properly advertising them. From beginning in a small way, his sales have increased to \$100 annually. He says: "It will be necessary to carefully tend, and properly transplant the hot-bed plants, that they may form large fibrous roots and short, stocky stems; to be very careful in getting the best varieties,

and the purest seed, and by judiciously timing the sowing and transplanting of the various plants, to keep the beds always occupied to the end of the season. I have one hot-bed 18 ft. by 3½, and another 25x6, and from these beds I last year sold, 1000 tomato plants, 600 celery plants, 500 asters, 100 pansies, 150 Japan pinks, 100 Winter Cherry, and a few Verbenas, Fuchsias and other bedding plants, and notwithstanding the comparatively large sum realized, I might have sold \$20 worth of cabbage and other hardy plants which I lost by cut worms and severe weather. Now, Sir, don't you, and some of your subscribers think that \$100 is worth trying for when it may be made with so much pleasure, and so little expense or trouble. I attend to sowing my beds and transplanting after factory hours, and wife attends principally to the sales. But don't think, dear Sir, that we deny ourselves any good thing from our garden just to make it pay; for besides what we sold last year from our farm of 16 rods, we raised ½ bushel of Isabella grapes, (and laid the foundation for future Delawares), many quarts of strawberries, 30 bunches celery, a bushel each of beets and turnips, (White French), tomatoes *ad infinitum*, 20 cauliflowerers, 30 cabbages, (and I must confess it, several pounds of tobacco,) a dozen fine squashes, besides enough peppers, salads, corn, beans, currants, and etceteras, and ½ dozen beds of as beautiful flowers as even you would wish to see."

What Grapes to Plant.

The Fruit Growers Meeting, having disposed of the pear question (as reported in the January *Agriculturist*, page 17,) next proceeded to the discussion of the varieties of *Grapes*, a brief summary of the first part of which is presented in the preceding columns. It was agreed to adopt four separate lists of three kinds in each. Special reference was had to a circuit of 100 miles around New-York City as the center, though the lists adopted, apply pretty generally over the country, exceptions being made for wide differences of climate, location, etc. The four lists are:

- I.—Three best kinds of grapes, sufficiently tested to warrant their recommendation for GENERAL CULTIVATION.
- II.—Three kinds known to be good in SPECIAL LOCALITIES, as on favorable soils or where sheltered, or under the ameliorating influence of large bodies of water.
- III.—Three kinds PROMISING WELL, but not so extensively tested as to warrant their being yet placed in the first or second lists.
- IV.—Three good WINE GRAPES for general cultivation.

After full discussion and comparison of views, during several weeks, the question was put to a direct vote by handing in written lists, the voting being done only by those qualified to do so by experience and observation. The votes stood: 19 for Delaware; 19 for Concord; and 13 for Hartford Prolific, and some for Diana, etc. On a division vote, as to which should be placed first, the vote stood 13 for Delaware, and 8 for Concord. This settled, the Concord received a unanimous vote for the second on the list. For the third, Hartford Prolific received 17 votes, and Diana 4 votes.

Over the second class there was also much discussion as indicated in our report. The Diana was placed first by general consent, all conceding it to be of excellent flavor, and a strong grower, but some complained that it did not ripen evenly. The Isabella was placed second,

but not without some protests, several gentlemen claiming that it should be discarded entirely. Its great success in the city yards of New-York and Brooklyn where many tons of it are annually grown, also at Croton Point, at Naples, N. Y., and elsewhere, was sufficient to save it from being thrown aside. It usually needs special protection of buildings, or of surrounding hills, or the influence of large bodies of water upon the atmosphere. The Catawba was placed third, with the same general qualification as the Isabella, and the additional one that it ripens later, and can not therefore be grown as far north. The first two lists therefore stand:

For General Culture.	For Special Localities.
1 DELAWARE.	1 DIANA.
2 CONCORD.	2 ISABELLA.
3 HARTFORD PROLIFIC.	3 CATAWBA.

The third and fourth lists are still under discussion at the time of this writing (Feb. 10th). There are several candidates for favor. Two or three would stand a fair chance for recommendation, but for the fact that the whole stock of vines is yet in the possession of a few individuals, and there is, at these meetings, a decided opposition to favoring individual interests. But of these lists hereafter.

Tobacco—Preparation of Seed Beds.

We have already received a number of essays on Tobacco Culture, but as all that are expected, have not yet come in, we are not able to publish the prize article this month. It being necessary to commence the preparation for the crop as soon as the ground can be worked, we give a few directions for the seed-bed. It is better to prepare the plot in the preceding Fall, but where that has not been done, the bed should be made ready as early as possible. A sheltered locality, where the cold winds are broken by woods or some other protecting objects, and having a good exposure to the sun, should be chosen. The ground should be made rich with plenty of hog manure, well spaded in; and then, just before planting, it should be covered with brush, which is to be burned on it. The burning of the brush serves to destroy the seeds of weeds, and furnishes a dressing of ashes, which is beneficial to the young plants. The time of sowing will depend upon the season and latitude: from the first to the middle of April being the time for Connecticut. About a square rod of ground is allowed for the seed bed for an acre. It would be better to lay this out in strips of about three feet in width, so as to allow the weeding to be done, without trampling on the bed. If the seed is good, a very small quantity will furnish plants for an acre, but it is best to have an abundance. A tablespoonful, well mixed with a pint of ashes or soil before sowing, will be plenty. The bed being thoroughly raked, the seed is sown, and the earth either rolled, or pressed down by a plank. When the sowing is made late, the seed is sometimes sprouted by moistening it, and covering with a damp cloth, and keeping it in a warm place. It takes about three weeks for the seed to germinate, and when it comes up, the plant is exceedingly minute. If the bed becomes dry, it should be watered with blood-warm water. The choice of varieties should be governed somewhat by the experience of others in the neighborhood, there being many local sorts, which are considered best adapted to certain districts. The leading varieties in the market are: the Connecticut Seed Leaf—valued as wrappers to cigars—the Kentucky, Maryland, Ohio, and Havana.

A Convenient Propagating Case.

The apparatus represented in the above engraving, invented by C. B. Miller, of this City, is designed to furnish a simple, cheap, and expeditious mode of propagating plants by cuttings, and starting seeds difficult of growth. It consists of a zinc vessel, *b*, for holding small pots which are set in the top, *c*. When in use, the hollow part, *d*, is to be partly filled with water, enough to nearly reach the bottom of the pots. The lower division, *e*, is also hollow, and its bottom rim fits upon the broad-based lamp, *a*. Air for the flame is supplied through the holes shown near *e*. The wick tube of the lamp is made very small, only large enough for a bit of cotton twine. Alcohol or burning fluid is used in the lamp. The bottom of the division, *b*, immediately above the flame of the lamp when the two parts are fitted together, is cone-shaped, to receive and retain the heat, and communicate it to the surrounding water. The small amount of steam generated, gives a uniform and gentle bottom heat, and sufficient moisture to the plants or seeds contained in the pots, thus affording the most favorable conditions for growth. If it be desired to keep a humid atmosphere about the cuttings, a glass tumbler is placed over each pot. The apparatus is neatly made, occupies but little space, and costs from \$2 to \$5, according to size. By its use, amateurs can supply themselves and their friends with many choice plants which would otherwise be unattainable save from the collections of professional nurserymen.

A Mess of Greens.

Most people highly enjoy a dish of greens. It is the first contribution of the season which the garden makes to the table, and it brings the assurance that Spring is at hand, and is a promise of more good things to come. Many persons rely upon the spontaneous growth of the fields and make use of dandelions, marsh-marigolds (improperly called cowslip), dock, and other things. These are better than nothing, but they are far inferior to what may be produced with a little care from the garden. At the head of the list we put Spinach, as the most delicious of all. This can be had very early by

planting in the Fall and giving a slight protection through the Winter. Or sow in Spring as soon as the ground is suitable and the rapidly growing plants will give an early supply to the table. Next, we place the Swiss Chard, a kind of beet which is grown for the leaves only, the root being small and useless. The outer leaves are pulled off for use and others quickly succeed them; a small bed will supply a family. Cabbage stumps, and turnips planted out, will yield numerous shoots which make good greens. They should be taken when still tender. Young beets, which are pulled up when the beds are thinned, are cooked with the roots on and are relished by many. Borecole or kale is a great favorite with the Germans. This is a hardy kind of cabbage which does not head, but forms a tuft of leaves which are eaten after they have been exposed to frost. Planted in the Fall and left out with little or no protection, it furnishes an abundant stock of greens early in the season. These are the principal varieties of greens grown in the garden, though others are occasionally used. The custom of boiling greens with pork or other fat meat is a bad one. The delicate flavor of spinach especially is destroyed in this way, and all greens are rendered less digestible. It is much better to boil them in pure water and dress them with butter and other seasoning as they are sent to the table.

Salsify or "Vegetable Oyster".

This vegetable is not as extensively cultivated as it would be, were it better known. It is grown with the same ease as carrots and parsnips, and helps make up an agreeable variety for the table. It should be sown upon good, rich soil, which should be worked deeply. Some English cultivators prepare the soil by bastard trenching,—that is, the top soil is removed a spade deep, an abundant supply of manure spaded into the soil below, and then the top portion is returned. By having the richest soil below, it is claimed that the roots have much less tendency to fork. We have found no difficulty in cultivating it, without this trouble, in soil prepared as for other root crops. The seed, which should be of the growth of the previous year, should be planted as soon as the soil becomes warm. Plant in rows 15 inches apart, and at the first weeding, thin out to 4 or 5 inches in the rows. The after-culture consists in keeping down the weeds until the leaves become so large that it is difficult to work among them with a hoe. The roots may be used when they are as large as the little finger; they increase in size until the growing season is over, but never grow to be much over an inch in diameter. The supply required for use during Winter may be buried in sand in the cellar, and the remainder left out to be dug in the Spring. Some of the finest plants should be left for seed, which is produced the second year. Birds, especially the yellow bird, are exceedingly fond of the seed, and, where these are numerous, it is difficult to secure it. The best way is to cut up the plant, before the seeds are fully ripe, and place them under cover to mature. The root is cooked in various ways. It may be boiled and mashed, and dipped in batter and fried, or cut in slices and stewed with the addition of milk and butter, after the manner of oysters. Boiled soft, first with water and then with milk, it makes a very good "oyster soup." The addition of a little salt codfish picked fine, makes the resemblance to oyster soup sufficiently near to warrant the name "vegetable oyster." When prepared for

cooking, it should be scraped and thrown into water; this will prevent the milky juice which the root contains from turning brown, as it will do if exposed for a long time to the air.

Chicory.

In a former volume of the *Agriculturist* we gave some articles upon the culture of this plant. It is now attracting so much attention that we present a brief account of it in reply to frequent inquiries. It is botanically known as *Chicorium Intybus*, and is sometimes confounded with the endive, which is a different species, (*Chicorium Endivia*.) The plant is a native of Southern Europe, and has become introduced into this country where, especially near the Eastern cities, it is a very common weed. The fleshy perennial root throws up a stem the second year which bears an abundance of pretty blue flowers, which open only in the sunshine. The general appearance of the plant in the wild state is well represented in the engraving; the detached flower is about half the natural size. Like the dandelion, to which it is closely related, all parts of the plant have a milky juice. In Europe the blanched leaves are used as a salad, but it is for the root that the plant is chiefly cultivated. The roasted root has long been used to mix with coffee, and, now that the real article bears so high a price, it is advocated as a substitute.

The culture is the same as that of carrots, about four pounds of seed being required for an acre. The roots may be taken up in the Fall or in the Spring before the flower stalk shoots up; some claim that the roots are of better quality when two or three years old. The root is

washed, sliced, and dried, and then roasted or burned. In England, 1 lb. of lard is added to 50 lbs. of the chicory while roasting, in order to improve its appearance. With regard to the propriety of using this as a constant bever-

age, we have already spoken pretty strongly. It is believed to excite the nerves unduly, to derange the digestive functions, producing headaches and other ills. Some say they have used it with impunity, and that those who are unpleasantly affected by coffee find the change to chicory to be beneficial. Much of the coffee sold ready ground, is more or less mixed with chicory, and some prefer it. Those who wish to try it as a substitute for coffee or to mix with it, can cultivate a small patch for the experiment.

THE HOUSEHOLD.

About Nutmegs.

"Spice to suit the taste" is a frequent direction in cookery, and the taste is very frequently for nutmeg. Like many other articles in every day use, which are so common that we seldom stop to think much about them, but little is generally known of the history of the nutmeg. The tree is a native of the Spice Islands. These were for a long time in the possession of the Dutch, who endeavored to confine its cultivation to three of the islands, and had the trees cut upon all the rest. Their intentions were interfered with by a bird which swallowed the nutmeg for its pulpy covering, and voided the nut unharmed; in this way the tree was carried to the neighboring islands. The Spice Islands fell into the hands of the English, who, during the time they had possession of them, distributed the plants to other countries, and the monopoly was broken up. The tree has considerable resemblance to a pear tree, and has fruit on it all the year round. The fruit is about three times as large as the largest one in the engraving, and consists of an outer husk which is somewhat woody when the fruit is ripe, at which time it splits in halves and exposes the nut. The nut as it comes from the husk, is shown in the engraving. It is enveloped with a peculiar covering; this covering, when removed and dried, is the spice known as Mace, which has a flavor quite distinct from that of Nutmeg, and is by many persons preferred to it. When fresh, the mace is of a bright crimson color, which turns to brownish, on drying. The nutmeg is still within another covering inside of the mace. To remove it from this, the nuts are exposed to a gentle heat, and when dried so that they will rattle, the shell is broken and the nutmegs removed. They are then put into lime, which gives them their whitened appearance; this is done to prevent the attacks of an insect which is very fond of them. The value of nutmegs depends upon the oil they contain: the oil is sometimes extracted by distillation and the nutmegs lined again and thrown into the market. This fraud can be detected by the experienced, by the lightness of

those which have been so treated. A sure way, and one which every one can practise, is to prick the nutmegs with a pin,—if the surface around the pin-hole appears greasy, the spice is good. Taken in large quantities, nutmegs produce narcotic effects similar to those of opium.

Drying Clothes—Air in Rooms.

Good housekeepers are anxious that washing-day should be a good drying day. It is a matter of common observation that on some days the clothes will dry more rapidly than on others. To understand why this is, we have to consider some of the relations of the air to moisture. The air possesses the power to take up water and hold it dissolved, as it were, in the state of invisible vapor. A given bulk of air can hold a certain amount of moisture, and when it has that, it can take up no more, the circumstances being the same. If the air has all the moisture it can hold, the clothes will not dry. If it has but a small proportion, they dry with a rapidity corresponding to the amount of watery vapor already in the air. When the clothes do not dry out of doors, they are brought into the house where they readily dry. Why is this, if the air within and without contains the same amount of moisture? This brings us to a remarkable change that heat effects in the power of air to take up vapor. The air at the freezing point of water can hold the 160th of its weight of vapor, and this capacity for moisture is doubled with every 27 degrees of additional heat. Air that is saturated with moisture and can take up no more at 40°, when heated to 67° is capable of taking up as much as it already contains, and wet clothing exposed to it, dries very rapidly. In the heating of our dwellings, by whatever means, the air has its capacity for moisture increased, and takes it readily from the objects in the room; the wood-work and furniture shrink and crack, and the leaves of the house-plants curl up and fall off, not because the room is overheated, but because the air is dry. The cold air from without, even though it may be damp at the time it enters the room, by heating, suddenly becomes capable of holding twice as much moisture as before, and everything in the room capable of yielding moisture, gives it up to supply the deficiency. Our bodies are unpleasantly affected by this dry air. Evaporation goes on with un-

ing is not entirely due to the presence of plants and flowers, but is in good part owing to the air which, to properly promote the health of the plants, is kept not only warm but moist; and it is this moisture, rather than the odors of the flowers, that makes the air of the green-house seem so balmy and spring-like. Let us take a lesson from the gardener in the care of our little human plants, and, whether the house be heated by stoves or by a furnace, be sure that the air is not too dry for health and comfort. There is a very curious way of telling the amount of moisture present in the air by means of a thermometer. It is no doubt familiar to every one that evaporation produces cold. The wetted hand, in drying feels cool, and if we pour alcohol, which evaporates more readily than water, over the hand, the cold will be much greater than with water. We have seen that water will evaporate more rapidly in a dry air than in a moist one, and that the more rapidly it evaporates, the greater will be the cold produced. Now we have only to take two thermometers and tie a bit of muslin around the bulb of one, and wet the muslin by dipping the covered bulb in water of the same temperature as the air of the room. If the air is as full of moisture as it can hold, no evaporation will take place, and the mercury in both thermometers will stand the same. But as we seldom find the air in this condition, either in or out of doors, the water will evaporate with a rapidity corresponding to the dryness of the air; the bulb will be cooled more or less rapidly, and the mercury will sink in the tube. Such thermometers have a table accompanying them which show, from the difference in the height of the two thermometers, how much moisture is present in the air.

Designs for Chain-Stitched Handkerchiefs.

To the Editor of the American Agriculturist.

While you cater for the boys' amusement, allow me to provide something for the benefit of the girls. Now that chain-stitched pocket-handkerchiefs are all the fashion, I dare say the girls, and women too, will be glad of some pretty patterns to mark them. Let them draw with a pencil the accompanying patterns, by placing the article to be worked, over the designs, and then chain-stitch in red marking cotton. The designs are suitable for braiding also, and to obviate the trouble of drawing the pat-

DESIGNS FOR CHAIN-STITCHED HANDKERCHIEFS.

due rapidity, and the skin becomes dry and unpleasant, thirst is excited and headaches are caused by it.

Every one who has entered a green-house, has noticed what a pleasant impression is produced; it seems like a sudden transition to Spring. This feel-

tern on cloth, tissue paper may be used. Copy the designs through, on to strips of thin paper, paste these on the cloth to be braided, and sew through braid paper and cloth. The paper may be torn out when the work is finished.

AUNT SUE.

Why Don't the Butter Come?

A correspondent of the *Agriculturist* writes that: "at times, particularly in Winter, great difficulty is experienced in bringing the butter. Sometimes the cream requires one or two hours' churning, and occasionally the butter appears in small globules, but can not be made to gather." The trouble probably arises from not having the cream at the right temperature when the churning is commenced. It should be at from 50° to 55° Fahrenheit. If lower than this, only a few of the minute sacs containing the butter will be broken, and the oily matter will coat over the remaining ones, forming the globules noticed by our correspondent. Try the cream with a thermometer before churning, and if too cool, set the cream vessel in hot water, until the proper heat is attained. If the cream be made too warm, the small sacs containing the butter break very easily, and the oily particles run together, making grease; in this case also, much butter will be lost, as the contents of the sacs first broken, will envelop the remaining ones, and many of them will not be ruptured. A correspondent, "Mary," at Harrisonville, Me., gives the following suggestion on the same subject: "In cold weather a double cream forms upon milk; the top layer thick and tough, with a thin stratum underneath. It is not fit to be churned in this condition; the butter will not come. Neither should it be mixed with sour cream which may be ready for churning. If I want to use such milk, I always place the cream in a separate vessel, and if needed to make out the churning, it is set near the fire, where it will sour quickly. When it is *all thickened*, it can be churned with the other cream."

Washing Comforters.

Mrs. Margaret R. Ball, Rush Co., Ind., writes to the *American Agriculturist* as follows: "Having noticed the statement that cotton comforters for bed clothing are not healthful, especially on account of the difficulty of cleansing them, I give my plan: First make them light enough to be quilted with a long needle. At any time they may need washing, but especially in Spring, spread them out on the grass before a heavy rain, and when thoroughly drenched, hang them on a line until dry. Then by beating them with a light rod, as a rattan, they may be made as light and pliable as ever." [It will require a very heavy shower to wash a comforter much soiled. Mrs. B. may intend to recommend to wash them first, and spread out afterwards. The whipping or beating will doubtless aid in making them more light and pliable. Comforters filled with cotton, are out of the question, however, at the present price of that article. We shall have to raise more sheep, and use woolen blankets.—Ed.]

The Clothes-Wringer a Good Thing.

We can not too frequently speak of the value of the modern household implement known as the Clothes-Wringer. From several years' experience with it in our own family, from the testimony of hundreds who have used it, and from the construction of the implement itself, we feel certain that it is worthy a place in every family where the washing is done at home. It is set upon any wash-tub, no matter what its form, and then by turning the crank with the right hand, and picking up the wet garments with the other hand, they are quickly passed through, and drop out into a basket, quite as dry as when twisted in the hands. The garments pass between two India rubber rollers which set close together, but which yield at different points, as needed, so as to squeeze the water out of the smallest pocket-handkerchief, or the largest garment. The fibers are not twisted and wrenched as in hand wringing, but are simply pressed between the yielding rubber, the water falling back into the tub. A child can readily wring out a tubful of clothes in a few minutes. It is in reality a clothes saver, a time saver, and a strength saver. The saving of garments will alone pay a large percentage

on its cost. We think the machine much more than pays for itself every year, in the saving of garments. There are several good kinds, nearly alike in general construction, but we consider it important that the wringer be fitted with *cogs*, so that they shall both turn invariably together, otherwise a mass of garments may clog the rollers, and the roller upon the crank slip and tear the fibers. The cogs of the wheels should be long enough to fit into each other when the rollers are pressed apart by large garments. Our own is one of the first made by the Metropolitan Washing Machine Company, Middlefield, Conn., and it is as good as new, after nearly four years' constant use. They have introduced many improvements since ours was made. We have given away several hundreds as premiums, (see premium No. 2, in our list), and shall be ready to furnish others in the same way, whenever desired. We have a contract, under which *this* premium will be continued for some time, whether the others are or not.

To Prevent Woolens Shrinking.

A correspondent, "M. B. B.," objects to the plan for drying stockings, by stretching them upon blocks shaped to receive them, published in a former number of the *Agriculturist*. Though it would prevent their shrinking, she thinks it would be too troublesome in a large family. She recommends the following plan: In doubling the stocking up to wring it, fold it at the heel, and lay the foot upon the leg. Then roll it tight, and wring it cross-wise. The same method is recommended by another housekeeper, H. A. Ingersoll, and we think there must be something in it. The latter lady writes, that in washing woolen fabrics, they should be put into very hot water, which may be allowed to cool until the hands can be borne in it. In changing the water for rinsing, be careful to have it several degrees hotter than that from which the articles were last taken. This will in some measure prevent fulling or shrinking.

Tim Bunker on the Farmer's Old Age.

"*Sallie Bunker Slocum*, is the baby's name," said Mrs. Bunker, as she took off her spectacles and laid down the letter from Shadtown, which I had just brought in from the Post Office.

"I like the name well enough, except the spelling of it," she continued. "Sally was my mother's name, it is my name, and my daughter's, and if they wanted to keep up the name in the family, I don't see why they didn't spell it in the old way. If I set out to do a thing, I would do it right."

"I suppose it is a little more genteel," I replied. "That is the way they spell it among the aristocratic families of the South."

"That is just what I don't like," said she. "It is a miserable affectation of women who read novels more than they do their bibles. We have no aristocracy up here, and judging from what I saw when I was down South, I never want to see any. Isn't this wretched war carried on to bolster up an aristocracy, and that a few families may live in idleness at the expense of the poor? I don't want to see any aristocratic trumpery on my grand-children. *Sallie* won't look well on a grave stone."

"What does Sally write about it?" I asked.

"Not a word about the spelling. She seems to think it is all the same. She writes: 'We carried the baby out to meeting for the first time last Sabbath, and it was baptized *Sallie Bunker*. We never thought of calling her any thing else, out of regard to you and grandmother, though we did not tell you at the time you were here, lest you should be too much puffed up with your honors. She is a nice child, and little Timothy thinks a world of her.' That is all she says about it. I shall write her immediately," said Mrs. Bunker, with emphasis, "that my name is not *Sallie*."

Now we do not always agree on small points, but on the larger matter of having grand-children, we see pretty much alike. It is one of the greatest comforts of old age to have children's children around us, to cheer us while we live, and to bear

our names and to take our places when we are gone. We can hardly have too many of them, and I shall not be very particular whether their names have a letter more or less, if we only have the children.

This is a matter of considerable solicitude, not only here in Hookertown, but in a great many farming towns around us. The present generation is getting pretty well along in life, and we do not know who is going to take our places. You would be surprised to see how few young men there are in the meeting-house on Sunday. The men who sit at the head of the pews are almost all gray haired, and some of them are about as white as snow. It looks a great deal worse than it did a year ago, before so many went off to the war. Uncle *Joatham Sparrowgrass* has no son to take his place, and *Seth Twiggs*, *Jake Frink* and myself have boys in the army, and a dozen more went from our parish. It is about an even chance, whether we ever see many of them again. The war bids fair to be a long one, and what the bullets don't kill, the hospital will be likely to finish. But then we ain't sorry the boys have gone, and if they don't come back, *we are going ourselves*, if the rebellion is not crushed. It is pretty certain that our farms won't be worth much to ourselves, or to our grandchildren, if *Jeff Davis* is going to rule. It is the old battle of despotism and liberty, and we are bound to see it through, whatever may be the cost.

We have got things fixed up pretty comfortable, and it will be pretty hard to go off and leave them, but we might say that, I suppose, when we start on a longer journey. We can't expect to stay here forever, and a few years more or less won't make any particular difference with us, when we get into the promised land. Most of us here in Hookertown have kept old age in view for a good many years, and I guess we are about as comfortable and jolly a set of old people as you will find among your hundred thousand readers. We have most of us got good houses that keep us just as comfortable and entertain our friends as well as a house that rents in the city for a thousand dollars or more. We are as independent as woodchoppers, on fuel, for if coal runs up to ten dollars a ton, as it has this winter, we can say to the coal merchant, "No you don't Mr.," and turn to the wood-pile. We have been using coal for several years, because it was cheaper than it was to hire labor, and chop and cart the wood. But there isn't a man of us but has a good wood lot, and I guess there is more wood in this town than there was fifty years ago. It is a great consolation to know where your fuel *can* come from, in case of a pinch. And then in case the house or barn wants repairs it is mighty convenient to know that you have a living lumber yard close by, where every shingle, plank, and timber you need, is on hand. Twenty acres of woodland that you have watched the growth of for forty years or more, is about as good as any bank stock I know of. I suppose I could sell the timber on any acre of mine for two hundred dollars, to say nothing of the fuel. That same land only cost me seventeen dollars an acre. Perhaps some folks who are in such a mighty hurry to cut off their forests, might as well stop and cipher a little.

And while I am talking of trees, as a shelter for old age, I want to say a good word for orchards, apples, and indeed fruits of all kinds. I waked up to planting apple trees when I was young, and I think I have now about as good an orchard as there is in town. With the low price of fruit this last year, it has brought me in over three hundred dollars, sold on the trees to the buyer. I only regret that I had not begun to plant pear trees sooner. They are quite as hardy as apples, yield as well, and sell for more than double. A man with a dozen acres in pears, of the right kinds, would have a comfortable income for old age, if he had nothing else. But aside from profit, a plenty of fruit in the family is a great comfort and luxury, and an important means of health. We have seen very little of the doctor in forty years, and we have had fruit in some shape every day in the year. Put these two things together: long lived people eat much fruit.

Perhaps we don't live quite so well out here on the farm, as some of the nabobs in the city, though

about that there is room for a difference of opinion. All the raw materials of their extra fixings come from the farm—poultry, eggs, milk, cream, butter and cheese, and the fine fruits. They have better cooks, perhaps, though some of us out here have things about as nice, in that line, as it is safe for sinners to enjoy. I should be loth to swap my cook for the best you have got in your biggest hotel. When Mrs. Bunker gets on her checked apron and spectacles, and lays herself out on a soup or a roast, you see, common cooks might as well retire.

In the matter of dress, we in the country are not quite so independent as we used to be, when there was a spinning wheel and a loom, in every house, and men wore the linen and woolen made at home, because they had nothing else. But we clothe ourselves easier now, for we can buy cloth a great deal cheaper than we can make it. But if the war continues, and prices keep going up, we may have to come back to homespun again, and then I guess the old folks will be about as independent as any body, for we know how to use the spinning wheel and loom. But that day is some ways off, I guess, judging from the finery we see in the Hooktown meeting-house on Sunday. That two-story bonnet of Miss Almada Georgiana Bottom has done the work for our young women. They tittered at it at first, but it was no use laughing at the fashions. They had to cave in, and the meeting-house on Sunday now looks like a big flower garden. The old ladies who were freest in their remarks, I notice have bonnets as high as the highest. I suppose I should not have said so, but I couldn't help asking Mrs. Bunker, as we started for meeting, if she would have the carriage top let down.

Hooktown, Yours to command,
February 20th, 1863. TIMOTHY BUNKER ESQ.

Night Clothing of Children in Winter.

"Let me tell you what Charlie wore at night last Winter," said an active young mother to me some time ago, speaking of her three year old boy. "He had on, besides his flannel shirt and drawers which he wears in day time, a pair of cotton flannel night drawers, two pairs of socks, a cotton flannel night gown, his double wrapper, and then a large shawl wrapped over the whole of it; for," said she, "I was afraid he'd freeze, for he would kick the covering off." I thought it no wonder. Being bundled up in that way, the weight of an ordinary amount of bed-clothes was unbearable, and the child became restless, and soon began trying to rid himself of some of the incumbrance, and the sudden transition from an overheat to comparative cold, made a cold sure consequence. Let the little fellows be stripped of everything at night, excepting the flannel shirt worn next to the skin, then put on a soft night gown reaching to the feet; add to this barely bed-clothing enough to keep them comfortable, and they will cuddle down and go to sleep, and never offer to kick the cover off. They will shiver a little at first, but they will soon get over that, and sleep soundly, and awaken bright and lively. MARY.

[In addition to the above, we suggest that it is advisable to change all clothing worn during the day, before retiring to rest. The under-garments having absorbed much perspiration, are good conductors of heat, and a person sleeping in them will feel, first an unpleasant chilliness, and afterward a disagreeable clammy sensation, as the clothing becomes warmer. If the supply of flannel shirts be scanty, or the extra washing be too much to allow two garments per week, it would be an improvement over the common custom, to wear one for the night the first week, and during the day the second week; thus giving each a daily airing.—Ed.]

659 Pies!

A correspondent writes to the *American Agriculturist*, that in his family, consisting of six persons, an account was kept of the number of pies eaten in one year; they amounted to six hundred and fifty-nine! [This is nearly one-third of a pie a day for each person. But how large were the

pies? If of the size of those sold by a Nassau-st. eating-house, cut into six pieces, at a sixpence each, they wouldn't do much harm, (nor good); but if like Savery's pumpkin pies, or those our mother used to make "out West," where we raised "some pumpkins," the other items of board in the family aforesaid would not cost much.—*Query, apropos.* Does the brief pleasure in eating pies pay for the trouble and expense of making them, and the dull feelings arising from trying to digest the conglomeration, yecept mince-pies, or the lard mixture called "short pie-crust?"—Ed.]

Adulterations in Coffee.

In ordinary times, roasted and ground coffee, especially that sold at low prices, was liable to adulterations. Now that the price of the berry has increased there is still greater inducement to mix foreign substances with it. We have before us a report of an examination made in London upon 34 samples of coffee, of all grades, and 31 of these were found to be adulterated. It is not to be supposed that Yankee dealers are any less ingenious than those over the water, and we have no doubt, from what we have seen of coffee bought ready ground, that adulteration is largely practised here. The articles used to mix with the coffee are often harmless in themselves, but are a fraud on the purchaser, as he pays for a cheap and worthless article at the price of a genuine one. The articles commonly mixed with coffee are chicory, peas, rye, and other grains, beans, and old ship biscuit. These may be mixed with coffee to a considerable extent, and it will still have the peculiar odor. To detect these adulterations with nicety, requires the skillful use of a microscope, but there are some rough tests which any one can make use of. Pure coffee, when put into cold water does not color it very rapidly, while the articles with which it is adulterated, readily give up their coloring matter. If then, water mixed with a sample of coffee, soon becomes dark, the presence of foreign substances may be suspected. The fragments of the coffee berry are quite hard, and remain so for some time after being wet with cold water. If a little be placed on a plate and moistened, and the separate particles tried with a pin or needle, the pieces of chicory, bread, etc., will be found to be very much softer than those of the coffee. The true way to be safe against adulterations is to buy the raw berry and roast and grind it. Then, if any mixture is needed, or desired, it can be added much more cheaply than to pay for it as coffee.

Scalded Emptyings, or Yeast.

Contributed to the *American Agriculturist*, by Mrs. David Brush, Suffolk Co., L. I. Take sweet, light rye dough, roll out and cut into pieces about three inches square, and dry on platters well floured, as quickly as possible, without baking them, turning them frequently. When thoroughly dried, put them in a small muslin bag, and keep in the flour barrel. When you wish to make emptyings, take, at night, one of the dried pieces, break it up and pour on tepid water enough to soak it. In the morning, drain it off and pour on a teacupful of tepid hop water, and thicken with rye flour and a half teaspoonful of ginger, to about the thickness of cream, and let it stand in a warm place until light. The next morning boil about 3 handfuls of hops in water enough to have 3 quarts left. Strain this, and pour it scalding hot on rye flour enough to make a very stiff batter; add one handful of salt. When the lumps are stirred out, let it cool until the finger can be borne in it. Then pour in the leaven you raised, mix thoroughly, set in a warm place until light, and carry to the cellar. It is ready for use at any time, wants no working up, and will keep six or eight weeks in cold weather, and three or four weeks in Summer. A heaped tablespoonful mixed with the bread or sponge, is the allowance for each loaf. By its use you will never fail to have sweet, light bread, as the writer knows by an experience of 16 years.

The leaven cakes will remain good for one or two years if kept as dry as flour should always be kept.

How to Make Soft Soap.

Contributed to the *American Agriculturist* by "Ann Eliza," Cold Spring, N. Y.: Take 5 lbs. potash, 5 lbs. grease, and 16 gallons of water. Break the potash in pieces the size of walnuts—if large, it will not dissolve so quickly. Put it in a clean tight barrel, melt the grease, and pour it in. Any grease will answer, as skimmings, old lard, etc. Have the water hot, and pour half of it immediately into the barrel, stirring it until the potash is dissolved, which will require from twenty to thirty minutes. Then add the rest of the water, stir again until thoroughly mixed, and afterward occasionally for three or four days. This will make about a half barrel of white soap, hard enough to cut with a knife. Should the potash be very strong, it sometimes requires more water, which may be known by small crumbling pieces remaining in the lye at the end of four or five days. In breaking the potash, be careful to prevent it from adhering to the clothing, as it would soon spoil the texture.

How to Make Hard Soap.

Seeing in a recent number of the *American Agriculturist* the call for Housekeepers' contributions, I send directions for making a soap that we have used for years: Take 3 lbs. of unslaked lime, and 6 lbs. of soda, and put in 5 gallons of water. When they are dissolved, pour off the water from the top, (throwing the sediment away,) and add to it 6 lbs. of fat. Boil till thick, pour in a tub, and when cold, cut in bars and dry. It is injured by freezing before drying. D. TAYLOR.

Hints on Cooking, etc.

Good way to Cook Eggs.—Contributed to the *American Agriculturist*, by "Mary."—Put into a spider not quite as much lard or meat drippings as for frying eggs in the ordinary way. While it is heating, break the eggs into a plate, and when it is hot slip the eggs into the spider evenly—not all on one side, or the grease will slip out from under them, and they will stick to the spider. Sprinkle them with pepper and salt, pour in nearly a teacupful of hot water, cover them quickly with a closely fitting lid, let them steam three or four minutes, when they will be found nicely whitened over the top, like eggs which have been cooked by breaking them into boiling water, and much more palatable than those poached without grease.

Pate de Veau.—Contributed to the *Agriculturist*, by a subscriber at Montrose, Pa. Take four pounds of the tender part of a leg of veal, chop raw, and with it mix six or eight small crackers rolled fine, two eggs, a piece of butter the size of an egg, slice of salt pork chopped fine, and enough salt and pepper to season well. Mix all well together, and mold into a loaf form; put small pieces of butter over the top, and grated bread; put on a dish with very little water, and bake two hours; when cold, cut in thin slices for tea, or use as a side dish at dinner. [This is similar to "Minced Veal" recommended in the *Agriculturist*, and which we find both convenient and palatable.—Ed.]

Ginger Snaps.—"A Young Housekeeper," recently sent to the office of the *American Agriculturist*, some excellent samples of this cake, with the following directions for making: Take 2 cups molasses, 1 cup lard, 1 tablespoonful ginger, 1 teaspoonful salt, 2 teaspoonfuls soda. Let these ingredients boil up once, then add flour until stiff enough to roll out, and bake in a quick oven.

Hominy Pudding.—It may not be known to all the readers of the *Agriculturist*, that pudding made of hominy is quite as good as that made of rice, and far cheaper. After having cooked the hominy by boiling in the usual way, add eggs, milk, sugar, and flavoring if desired, as in making rice pudding. We have tried it, and know it to be good.

A MOUSE'S DREAM—THE CAT IN COURT.

(Designed and Engraved for the American Agriculturist.)

The Editor with his Young Readers.

A fine time these mice are having. Their old enemy, the cat, is securely muzzled, bound hand and foot, and led in triumph to be tried for high crimes against the mouse community. The judges have taken their seats in due form, the clerks of the court are ready to record the testimony, the armed guards are prepared for any emergency, and the lookers on are in high glee. Our artist calls it the *Mouse's dream*; we suspect he himself must have been visiting dream-land. However, if mice do ever dream, they might be supposed to have some such a vision in sleep. No doubt the little fellows would be as happy over the prospect, as boys we have seen—grown-up ones as well as children—dreaming with their eyes open, and their hands idle, about triumphing over supposed obstacles to their happiness. And it would be as profitable in one case as in the other. The mice will awake to find the cat as active, powerful, and cruel as ever; so the idle dreamers about lucky numbers in lotteries, plenty of money without hard work to get it, respectability and honor without living to deserve it, will learn that such acquisitions are not to be had by dreaming for them.

An Ingenious Boot Black.

The street Boot Blacks are one of the "institutions" of New-York, as well as of some other large cities. You see them on the side-walks, in and around the hotels, and frequently on the ferry boats. They carry a box containing their "kit of implements"—the brushes, blacking boxes, etc. This is suspended by a strap over the shoulders, and when a customer nods assent to their generally polite invitation: "Black yer boots?" or "Shine up, sir?" they quickly set down the box for your foot to rest on, drop upon their knees on the pavement, and work as rapidly as possible, so as not to detain their patrons. They first turn up the pants to keep them from being soiled, then with one brush they clean the boots, with another apply the blacking, and with two others, one in each hand, polish away. They return a "thank ye" for the half dime, or dime, given for their labor. These boys are generally so polite and so industrious that we rather like them, and sometimes take a "shine up" just to see them work, and to chat with the smart little fellows.—Here is a case illustrating their ingenuity: A well dressed man standing at a hotel door not long since, was hailed by one of them with the usual question, "Shine up, sir?" "What do you charge for blacking boots?" asked the man, who was somewhat noted for stinginess. "Five cents," was the reply. "Too much, too much, I'll give you three cents," said the man. "All right," said the youngster, and at it he went with might and main, and very soon had one boot shining like a mirror: but instead of commencing on the other, he began to pack up his brushes. "You haven't finished!" exclaimed the man. "Never mind," replied the boot-

black, with a twinkle in his eye, I won't charge you any thing for what I've done; there comes a customer who pays." The man glanced at the shining boot, then at the other, which was rusty and bespattered with mud, thought of the ridiculous figure he would make with one polished boot, and amid the laughter of the bystanders agreed to give the sharp boy ten cents to finish the job, which he did in double quick time and with great pleasure.

Good Manners—An Anecdote.

A correspondent of the *Agriculturist* relates the following incident, which he says occurred some years since in the State of Rhode Island. Colored persons are allowed to vote there, and to hold office, if elected. On one occasion, Mr. R., a very pompous, but not very popular man, desiring to be chosen Inspector of Elections, gathered his friends around the polls early on the morning of election day—the custom being to select an Inspector by vote of those happening to be present at the opening of the polls. Some mischievous young men, who disliked the pompous candidate, had heard of his plans, and they were also present with a large party, and, to his great disgust, they gave a majority for a huge, burly, but good-natured negro, well known to the citizens. When the voters came up to deposit their ballots, as usual each one took off his hat in presence of the Inspector. Soon Mr. R. approached. "It is customary to take off the hat when voting," said he, "but in this case I don't know about it." "Oh!" immediately replied the colored man, "jest as you please; it depends on a man's brought up; dere's Mr. S. and Mr. B., (naming two wealthy citizens), dey took off dere hats, but if a man has'n't been brought up to manners, why we 'seuse him." The roar of laughter which followed, so discomfited Mr. R., that he hastily left.

Robbed Advantageously!

A lady riding in a rail-car in Brooklyn recently, was somewhat crowded upon by a well dressed man, who soon after left the car. She found he had abstracted her purse containing \$7, but in doing so, he unintentionally slipped off into her pocket a valuable diamond finger ring, for which a friend, a jeweler, gladly gave her \$100, leaving her a gain of \$93. The man has not called for his ring.

A Thoughtless Boy Punished.

"I shall never forget," writes a correspondent of the *Agriculturist*, "an incident of my childhood by which I was taught to be careful not to wound the feelings of the unfortunate. A number of us schoolboys were playing by the roadside one Saturday afternoon, when the stage coach drove up to a neighboring tavern and the passengers alighted. As usual we gathered around it to observe them. Among the number was an elderly man with a cane, who got out with much difficulty, and when on the ground, he walked with the most curious contortions. His feet turned one way, his knees another, and his whole

body looked as though the different members were independent of it, and of each other, and every one was making motions to suit itself. I unthinkingly shouted 'look at old rattlebones!' and the other boys took up the cry with mocking laughter, while the poor man turned his head with an expression of pain which I can never forget. Just then, to my surprise and horror, my father came around the corner, and immediately stepping up to the stranger shook his hands warmly, and assisted him to walk to our house, which was at but a little distance. I could enjoy no more play that afternoon, and when tea-time came, I would gladly have hid myself, but I knew that would be vain, and so tremblingly went into the sitting room. To my great relief, the stranger did not recognize me, but remarked pleasantly to my father as he introduced me, 'Such a fine boy was surely worth saving.' How the words cut me to the heart. My father had often told me the story of a friend who had plunged into the river to save me as I was drowning, while an infant, and who in consequence of a cold then taken, had been made a cripple by inflammatory rheumatism; and this was the man whom I had made a butt of ridicule, and a laughing stock for my companions. I tell you, boys and girls, I would give many dollars to have the memory of that event taken away. If

ever you are tempted as I was, remember that while no good can come of sport whereby the feelings of others are wounded, you may be laying up for yourselves painful recollections that will not leave you for a lifetime."

The Boy's Reproof.

A minister in a country village received his supply of milk from one of his deacons, and his son Robert, about ten years old, was sent for it daily. A railroad had recently been built in that vicinity, and the boys had learned to imitate the whistle. When Robert was within a few rods of the deacon's house, he used to give a loud "too-o-o-t," to let them know he was coming, so that the milk might be ready. It happened that milk was needed for a young child one Sunday afternoon, and Robert being sent for it, unthinkingly gave his usual too-o-o-t. Upon entering the house the deacon said to him rather severely, "Robert, the cars do not run on Sunday." Presently the deacon remembered that he had not seen the weekly paper which the minister was accustomed to lend him. "Robert, said he, "did you bring the newspaper?" The little fellow very archly, but respectfully replied: "The cars do not carry the mail on Sunday sir!" The deacon was fairly beaten with his own weapons.

An Unfortunate Mimic.

A correspondent of the *Agriculturist* writes: "A young lad of this neighborhood whom we will call Thomas, has practised imitating the sounds made by various animals, until he has become quite expert at it. He often sets the hens to cackling, the dog to barking, or the cow to running for her calf by mimicking their cries. Being full of mischief, he loves to play practical jokes. On one occasion he led a hunter a chase of more than a mile through the woods by imitating the chattering of a gray squirrel, and keeping just out of sight of the sportsman. He was partly cured of such practices, however, by the following occurrence. A man living near had a great aversion to cats. Thomas, knowing this, loved to tease him by going near his windows in the evening, and setting up a complete concert of squalls, as though all the cats of the neighborhood were trying their vocal powers. One night he had just commenced this performance, when to his horror a passing dog attracted by the noise, leaped over the fence and sprang toward him. Away he ran, shouting for fear, the dog in full chase after him. He succeeded in getting near his own door, when the dog was just upon him, and he was obliged to face him or be bitten. He swung his cap, kicked desperately, and managed to keep him at bay, at the same time shouting for help. His father heard the noise, but merely remarked, 'Oh, it's only some of Tom's nonsense,' and paid no attention to it. Presently there was a loud scream, which really alarmed him, and hastening out he found the dog had bitten his son severely, and the animal was with difficulty driven off."

Wooden Flowers, and Real Ones.

The engraving, fig. 1, represents a flower and leaf from a bouquet, ingeniously made from wood, by Mr. John Seivers, of Hackensack, N. J. The material is white and red cedar. In order to get them up, a block, (fig. 2), is first whittled into the shape of the leaves of the flowers, and this is carefully split up into a number of thin plates, or leaves. These are then to be put together: for this purpose a center piece is whittled out as in fig. 3, and the separate leaves are glued, each into a notch in the side of this. A slender twig, with the bark taken off, is fitted in for a stem, and the flower is done. Leaves are made in a similar way. The one in the engraving has its separate parts made in the same manner as those of the flower; these are afterward attached to the leaf stalk, by slitting it at the proper places and gluing them in. Those who undertake to make artificial flowers from any material, should carefully study the real ones. No fanciful forms can be as beautiful as those made by nature. Upon pulling a natural flower to pieces—unless it be a very double one—it will be seen that the different parts occupy a certain position; now to make an artificial flower like it, the parts must be exact copies of the natural one, in size and shape, and must be of the same number, and be put together in the same position as they are in the real flower. We would not advise our young friends to spend much of their time in trying to make imitations of natural flowers. They would take much more pleasure in trying to find out how the Great Workman made the real flowers—in seeing how every plant after it starts from the seed, builds up a more wonderful structure than our best skill can imitate.

Would not some of our young readers—and old ones too for that matter—like to know more about plants? Now that Spring is coming, and the buds on the trees will soon begin to swell and unfold, and the seeds will soon be put in the ground, we intend to talk a little about what is going on all around us. Almost all boys and girls have some little spot or corner which they call their garden; they find much pleasure in working in this, in planting the seeds, and watching the growth of the plants from day to day. Let us see if we can not make this little garden more pleasant by showing you things you never noticed before, and that upon a small spot of ground there are wonderful and curious things if you only know how to see them. We intend next month to tell you how to plant the garden, and then how to watch what is going on there, from month to month. So look out for the "Boys' and Girls' Garden."

Amusing Trial of Skill.

Tie a common finger ring to a thread and let it hang at a convenient height, with the opening toward the one who is to make the trial. Let him take a small crooked stick, and stand far enough from the ring to just reach it. Now ask him to close one eye and thrust the stick through the

ring; he will seldom succeed without trying several times. A person with only one eye would do it easily; those accustomed to use two eyes in judging of distances, can not readily use one with the same accuracy.

A Subscriber Every Minute!

A mail-clerk in the office of the *American Agriculturist*, who has a penchant for arithmetical calculations, has been amusing himself over the subscription-books. He reports as the result, that since last November the number of subscribers coming in has averaged a good deal more than one for every minute! reckoning ten full hours a day. This does not include more than ten thousand previously received for this year. Up to this date, (Feb. 17,) we have already printed for subscribers, over sixty thousand copies of the January and February Numbers, and shall print many thousands more of them from the stereotype plates, as the tide still flows in at the rate of 200 to 600 a day, and there will be only a gradual decline, if any, for two or three months to come, judging from previous years. Really, it looks as if we should get through this year with a "whole skin," notwithstanding the severe scarifying we, in common with other publishers, have had to endure from the paper manufacturers.

The Game of Rhyming Definitions.

Any number may take part in this play: the more the merrier. The leader selects two words which rhyme together, and mentions one of them; the company are to guess the other, but instead of naming it, they must in some way define it, requiring the leader to give the word they have guessed. Thus, for example, John says "find me a word to rhyme with gate." "Is it what school-children write on?" asks Julia. John answers: "It is not a slate."—George asks: "Is it a period of time?" "It is not a date," is the reply. "Is it to be not punctual?" "It is not late." "Is it yearly interest on money?" "It is rate." Then the one who guessed correctly becomes leader, and gives out the next word. Sometimes one of the company indicates a word which the leader cannot name; in this case the leader must pay a forfeit. The game is a very pleasant one, and is also useful to instruct the players in the use of words.

The Bouquet Portraits Explained.

Last month, page 57, we published the singular Bouquet, representing profiles of some of the Napoleon family. It was supposed that every one would see the figures, but it turns out that this was not the case with many persons, as not a few have called or written for an explanation. We have therefore added a few lines which will make the matter plain. After seeing the figure above, it will be interesting to turn back to page 57 and look at the original picture, and see how clear the white profiles stand out—not the black ones that so many tried to find. The upper left-hand figure is for Napoleon I.; the right hand upper one for his wife Maria Louisa; and the centre figure is for their son, frequently called Napoleon II.—the present Emperor of France having assumed the title of Napoleon III. [Correction.—By a slip of the pen, Maria Louisa was erroneously printed Maria Antoinette, in a few of the first copies of the previous number; it was soon noticed and corrected in the plate.]

New Puzzles to be Answered.

No. 31. Illustrated Rebus; good advice for the times.

No. 32. Illustrated Rebus; to be well remembered.

No. 33. Mathematical Problem. A tree 100 feet high broke and fell, (hanging to the stump); the top struck the ground 40 feet from the base; how high did it break?

No. 34. What word in the English language contains all the vowels in their regular order?

Answers to Puzzles and Problems in February No., (page 57).—No. 28. *Arithmetical Problem*. The bond would be liquidated in 31 years, nearly. (Some unknown correspondent sent in a solution exhibited in tabular form with great neatness.)—No. 29. *Cent Puzzle*. The date is a fruit; two lips (tulips) are flowers; the temple is a house of worship; the hair (hare) is an animal; the ear is a quantity of grain; locks are a protection against thieves.—No. 30. *Transposition*. The letters of new door may be transposed into the words, "one word."—The following have sent in correct answers up to the date of Feb. 16, viz.: Wilson Holmes, to Nos. 24, 26; A. Hageman, 24, 25, 26, 27; James H. Wing, 31, Orison B. Smith, 29; Daniel Gravatt, 30; F. W. Winship, 24; Sarah H. Barnard, 27; Zimri E. Hinchaw, 24, J. Cox, 30; J. Garrison, 28, 29, 30; Elmore Decker, 28, 30; Rufus W. Weeks, 28, 30; A. B. Coggeshall, 30.

PREMIUM LIST—1863.

Good Pay to Voluntary Agents who attend to Collecting and forwarding Clubs of Subscribers to the *American Agriculturist*.

(Premiums open to all who Desire them.)

The following articles are still offered, with no changes from last month, except in books. See remarks on p. 68. To all who take the trouble to collect and forward clubs of subscribers, we offer a remuneration in the form of first-rate articles, as named below. (The pay thus offered is much larger than we could give in cash, as we get these articles on extra good terms when for premiums.)

WE WISH IT DISTINCTLY UNDERSTOOD that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand thing, will be sent out, but each article offered, is the best of its kind. Clubs need not be all confined to one Post Office.

For other items, and for a full description of the premiums, see page 60 of February *Agriculturist*.

Table of Premiums for 1863.

Names of Premium Articles.		Price of Premiums.	Names at \$1 each.	Names at 50 cts. each.
1—Good Books—See terms below.				
2—Best Family Clothes Winger.	\$7 50		19	40
3—Nonparel Washing Machine.	\$16 00		35	75
4—Sewing Machine, (Wheeler & Wilson).	\$45 00		90	130
5—Sewing Machine, (Wileox & Gibbs).	\$35 00		69	98
6—Aneroid Barometer.	\$7 50		20	46
7—The Aquarius.	\$10 00		22	47
8—Five Octave Melodeon (best).	\$75 00		125	237
9—1½ Octave Melodeon (best).	\$60 00		104	182
10—Four Octave Melodeon (best).	\$45 00		90	130
12—Worcester's Unabridged Dictionary.	\$8 50		25	53
13—Six baek Volumes <i>Agriculturist</i> .	\$6 72		19	35

Premium No. 1—Good Books.

Any person sending 16 or more subscribers, may select from our book list, (page 91,) to the amount of 12½ cents for each name, at the club price of 80 cents, or to the amount of 33½ cents for each name at \$1. Farmers' Clubs have frequently joined together and obtained a good library through these premiums. N. B.—The books will be delivered to the recipients, (by mail or express,) free of all cost.

See Book List page 91, for several changes in price. The prices of the books have been advanced by the publishers, (not by us) and we are obliged to conform to their rates as they charge from month to month. Books called for under this premium will necessarily be at the new rates.

Business Notices.

Eighty Cents a Line of space.

New-York State Agricultural Society,
Rochester Fair, 1862.

I hereby certify that JAMES PYLE, of New-York, was awarded a special prize at the State Fair at Rochester on his O. K. Soap, Dietetic Saleratus, Cream Tartar, Baking Soda, and various other articles of exceeding great merit—and the Executive Committee of the Society give special commendation for the great excellence of the articles exhibited.

In witness whereof I have hereunto subscribed my name, and affixed the official seal of the Society.

L. S. } B. P. JOHNSON, Secretary.

Market Review, Prices, Weather, etc.

The condensed tables above indicate a very large falling off in the receipts of Flour, Wheat, Corn, Barley and Oats, for the month, as compared with the previous month; and also as compared with the same time last year, excepting Flour, Corn, and Oats, which have come in more freely this year. The sales of Flour, Corn, and Oats, on the contrary, have been greater. The increased sales of Flour are quite marked, being more than doubled as com-

pared with the previous month. The sales of Wheat for 28 business days ending February 19th this year, amounted to 2,416,000 bushels, against 914,000 bushels for 25 business days ending February 19th, last year. In table 3, it will be seen that so far this year, the exports of Flour and Corn have been less than in 1862, while the exports of Wheat have been larger by 607,545 bushels..... The table of CURRENT PRICES shows a decided advance in almost all kinds of farm produce, and especially so in Flour, Wheat, and Corn. This has been in part due to the advance in gold and foreign exchange. We have previously shown why this should be so, why exporters can afford to give higher rates for anything that can be sent abroad instead of gold, and how farmers are directly benefited, much more than any other class, by the premium on gold. Every producer who has debts to pay, or purchases to make of articles not advancing materially in price, is a great gainer by the high rates for gold and Sterling Exchange. The fall in gold last week checked the market, but just now there is decided activity, and a heavy demand from shippers, home buyers, and speculators. The shipments are large, and appear likely to continue so for some time to come. During the week ending February 11th, the exports of produce and miscellaneous goods (not including gold) amounted to the extraordinary sum of \$5,154,962, against \$2,144,476 same week last year, and \$2,664,873 the corresponding week of 1861. Of the exports, to the single port of Liverpool, there were shipped \$1,893,135; and to London, \$633,962. Included in the exports to Liverpool were nearly 23,000 barrels of flour, 406,000 bushels wheat, 126,000 bushels corn, and a very large quantity of provisions; to London, 22,000 barrels of flour, 150,000 bushels wheat, and provisions to the value of nearly \$146,000. During the week ending yesterday, the exports were again very heavy, amounting to \$4,986,632, against \$2,855,129 the same week last year, and \$2,278,902 the corresponding week of 1861..... The Cotton market has been more active, and prices have very rapidly advanced, closing however, rather tame. There has been unusual activity in the Provision Market, heavy purchases having been made for export, and prices have steadily favored sellers..... Wool has been in very brisk request, and prices are much higher, closing buoyantly and irregularly, with reduced stocks of all descriptions in market. Manufacturers have purchased heavily, as also parties buying on speculation. The activity has been greatest in foreign Wools..... The movements in other kinds of domestic produce and general merchandise have been on a liberal scale, and at advancing rates, as shown in the tables.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been well supplied during the past month, averaging 4,812 per week, or 300 more than the weekly average for all last year. But prices have advanced 5¢, with brisk sales generally. At the market on Feb. 17th 5,275 head were offered, following a supply of 5,987 at the previous market. A few extra animals sold at 12¢. per lb. for the dressed weight; good to prime bullocks at 9¢. @ 10¢.; fair to good at 8¢. @ 9¢., and poor grades at 6¢. @ 7¢. Average of all sales—8¢. None left over.

Veal Calves.—Receipts have averaged 341 per week. Prices have advanced 1¢. per lb., live weight, and the demand is at present unsupplied. Fat calves are now worth 6¢. @ 7¢. per lb.; fair veals 5¢. @ 6¢.

Sheep.—Receipts have been 6,403 per week for five weeks. Since our last report they have advanced in value more than 1¢. per lb., live weight, owing to higher prices of pelts, which are now worth \$3 75 @ \$4 00 each, or more than the dressed carcass. Large fat sheep have sold in lots, at prices equivalent to 8¢. per lb., live weight. With 8,543 on sale this week, prices declined 1¢. per lb., fat sheep selling at 7¢., and extra sheep 7¢. Several droves, amounting together to 1,000 head of fair sheep, averaged about \$7 00 per head.

Live Hogs.—Receipts have been lighter, the average for five weeks past being 26,532 per week. In common with all other kinds of live stock, hogs have advanced 1¢. in price. Prime, fat, corn-fed hogs are now selling at 5¢. @ 5½¢. per lb., live weight; medium hogs, 5½¢. @ 5¾¢., and still-fed 4½¢. @ 5½¢.

The Weather has been very mild for Winter, more like April than February. Our DAILY NOTES CONDENSED, read: January 20, warm, cloudy—21, rain 22, cloudy—23, clear, fine—24, cloudy—25, warm, clear P. M.—26, light rain P. M. and 27, 28, N. E. snow and rain—29, two inches snow A. M., clear P. M.—30, 31, clear.—February 1, cloudy, rain at night—2, clear, warm—3, colder—4, coldest day, mercury 4° in the morning and 2° at night—3 light snow, 3°, very cold A. M., thaw P. M., rain at night—6, N. E. rain—7 to 9, fine, mild days—10, clear—11, mild, snow and rain at night—12, rain—13, clear—14, cool, rain at night—15, rain—16, clear, fine—17, cloudy A. M., light snow, P. M.—18, clear A. M., cloudy P. M., rain at night—19, heavy rain.

Rain Fall Jan. 15th to Feb. 15th, 6.16 inches!—Barometer changes remarkable—Feb. 5th, mercury up to 30.50, the highest point during 30 years past.

Valuable Farm near New-York for Sale Cheap.

An excellent farm, 3 miles from Tarrytown, in Westchester County, 25 miles from the City Hall of New-York, will be sold at a great bargain, owing to the peculiar circumstances of the proprietor. (Title indisputable.) It contains a good house, three barns, out-buildings, excellent orchard, etc., etc. Will be sold, on easy terms of payment, for ten thousand dollars, (which is much below its real value.) For particulars address Box 24, Tarrytown P. O., or inquire of P. S. TAGGART, at 126 Duane-st., New-York City.

FARMS FOR SALE.—The finest farm of its size, 150 acres, in Westchester County. Also, several farms and country seats on the Hudson River. Several fine farms on Long Island Sound. Farms in New-Jersey, and in this and Western States, for sale by
S. COCKCROFT, 4 Pine-st., New-York.

HOME WANTED ON A FARM, FOR A SMART BOY, 13 years old. Call or address
C. THEELER, No. 363 Adelphi-st., Brooklyn, N. Y.

A FIRST CLASS COMMERCIAL COLLEGE

with Bank, Model Store, Offices, and all the approved apparatus, under able and accomplished Professors, has been established in connection with the

FORT EDWARD INSTITUTE.

\$20 pays for Graduates Course, whether the time occupied be one term or more. \$40 pays for 14 weeks Board, Washing, Fuel, Common English Branches, and Lectures. The connection of the two Institutions affords better advantages, and at lower rates, than any mere Commercial School. 125 young men are now pursuing commercial studies.

SPRING TERM, MARCH 26. Address
REV. JOS. E. KING, Fort Edward, N. Y.

Great International Agricultural Exhibition,

TO BE HELD AT

Hamburg, Germany, in July, 1863.

The attention of Agriculturists, Growers of Stock, and Manufacturers of Agricultural Implements, machinery, and others interested in Agricultural Products, is called to this Exhibition, which will probably exceed in interest and magnitude any Fair of the kind ever held.

Every facility will be afforded for the cheap transportation of all contributions to the Exhibition, as well as to the delegates from the several State Societies, and others connected with the Exhibition.

All applications for entries must be made to the only authorized Agents undersigned, before the fifteenth day of April next, who will furnish programmes and any information required.
AUSTIN BALDWIN & CO.
Sole Agents, 72 Broadway, New-York.

335 BROADWAY, NEW-YORK.

THE BEST DICTIONARY OF THE
ENGLISH LANGUAGE.

The Royal Quarto Dictionary of Dr. Worcester is a massive volume of 1854 pages, a monument of patient toil and deep research. Its verbal opulence swells to *One Hundred and Four Thousand Words*, giving their etymologies, their pronunciation, complete and elaborate definitions, critical remarks on the pronunciation, the etymology, the grammatical form and the use of words, with copious citations from the best writers of every age of English literature.

It contains nearly 20,000 more words and meanings than any other *English Dictionary*; 5,000 words synonymized, 1000 superb illustrations, numerous tables of proper names pronounced, &c., &c.

Unquestionably much superior to any other general Dictionary of the language.—G. P. MARSH, LL.D., Author of *Lectures on the English Language*.

I have for several years used Webster, as the best Dictionary of its kind—always excepting its orthography.—But I regard and recommend for our schools and public institutions Worcester's Dictionary, as a very great improvement upon that of Webster's pictorial edition.—E. KINGSO, LL.D., Superintendent of Public Instruction for Upper Canada.

More complete and exact than any of its predecessors.—W. WREWELL, LL.D., Master, Trinity College, Cambridge, and author of *History of the Inductive Sciences*.

It is the most complete and practical, the very best as well as the cheapest English Dictionary that I know.—JOS. BOWDITCH, D.D., Professor of Anglo-Saxon, University of Oxford.

Thoroughly trustworthy.—C. C. FELTON, LL.D., late President of Harvard College.

The best existing English Lexicon.—LONDON ATHENÆUM.

Singularly cheap, full, and trustworthy.—LONDON EXAMINER.

ALLEN'S PATENT CYLINDER PLOW.

This Plow derives its name from the form of the mold board, which is a segment of a perfect cylinder, with its ends cut in the style of ordinary mold boards. Its lines are thus always horizontal to the surface of the land, and consequently turn the furrow slice with the same uniformity as a wheel on its axle, and with the least possible friction. The friction is still further reduced, by the peculiar arrangement of the POINTS or SHARES, and LAND SIDE, which, combined with its other improvements, reduces the draft from ONE-FOURTH to ONE-THIRD LESS than that required by the best class of plows now in general use. For lightness of draft, simplicity of construction, ease of holding, and certainty of turning all soils of any required depth and width, it far surpasses any other plow.

Price of No. 0, is \$7.00; No. 1, is \$9.00; No. 2, is \$10; No. 3 is \$12; with one extra polished share for each plow. Price, extra, of Skim or Front Plow, \$1.50; Wrought Side Coultter and Clamp, \$1.25; Wheel, \$1.00.

All the above Plows are polished, strong, and highly finished, and are warranted to give entire satisfaction when properly managed. Polished Steel Plows can be furnished of each of the above sizes.

Also every style of the latest improved PLOWS, HARROWS, CULTIVATORS, and a full assortment of AGRICULTURAL and HORTICULTURAL IMPLEMENTS; FIELD and GARDEN SEEDS; PERUVIAN and MANIPULATED GUANO; SUPERPHOSPHATE, guaranteed to be the best in the market, and perfectly reliable; Poudrette; Plaster of Paris, &c.

INGERSOLL'S IMPROVED HORSE AND HAND POWER

HAY AND COTTON PRESSES.

These machines have been tested in the most thorough manner throughout this and foreign countries to the number of over 1300.

The Horse Power is worked by either wheel or capstan, and in many respects possesses unequaled advantages. We invite those wanting such machines, to write for a catalogue containing full information, with cuts, prices, etc., or call and examine personally.

Orders promptly attended to, by addressing
INGERSOLL & DOUGHERTY, Greenpoint, Kings Co., L. I.

ONION CULTURE—Third (new) Edition.

This work comprises in 32 pages all the particulars for successful Onion Culture, from Selection of Seed to Marketing the Crop—being the practical directions given by seventeen experienced Onion Growers, residing in different parts of the country. Price 21 cents (or 7 stamps), sent post-paid. Address Publisher of *Agriculturist*.

PHYSIOGNOMY, or "Signs of Character," PHYSIOLOGY, the Bodily Functions; PHRENOLOGY, the Soul; ETHNOLOGY, or Natural History of Man, are topics elucidated in the ILLUSTRATED PHRENOLOGICAL JOURNAL for 1893. No. 1, 10 cents, or \$1 a year. Address FOWLER & WELLS, 308 Broadway, New-York.

A Manual of Agriculture

FOR THE

SCHOOL, THE FARM, AND THE FIRESIDE.

By GEORGE B. EMERSON, author of a "Report on the Trees and Shrubs of Massachusetts," and CHARLES L. FLINT, Secretary of the State Board of Agriculture, author of a Treatise on "Milk Cows and Dairy Farming," and "Grasses and Forage Plants," etc.

Though prepared more expressly for the use of schools, the Manual was also designed for general use, as an elementary and comprehensive treatise on scientific and practical agriculture.

Price 75 cents. Copies sent by mail, postage paid, on receipt of price.

Every farmer and every man who cultivates a garden should have this book. BREWER & TILESTON,
131 Washington-st., Boston, Mass.

THE "EXCELSIOR BURR STONE MILLS,"

AND

ANTI-FRICTION

HORSE POWERS,

Have taken the HIGHEST PREMIUMS WHEREVER EXHIBITED! NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS in 1891.

THE MILL may be driven by horse, water, or steam power, does its work equally as well as the best flat stone mills in milling establishments, and requires but *one-half the power* to do the same amount of work. They are made in the best manner, and will last *thirty years*, and cost *nothing for repairs*.

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT. more work than ANY OTHER POWER IN USE.

EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

Liberal discount to dealers—Agents wanted. State, County, and Shop Rights for sale.

THE CRAIG MICROSCOPE.

This is the best and cheapest microscope in the world for general use. It has just received the First Premium—Silver Medal—at the Ohio State Agricultural Fair. It requires no focal adjustment, magnifies about 100 diameters, or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of \$2.25, or with six beautiful mounted objects for Three Dollars. Address HENRY CRAIG,
182 Centre-st., New-York.

MR. HENRY CRAIG—Dear Sir: I have received the Microscope you forwarded to me, and am well pleased with it. It is a valuable instrument, one that should be in the house of every family, where they can appreciate its value. The study of nature is one that is interesting and useful. Being in company with some of my friends the next day after I received my Microscope, I was compelled to part with it.

Please find inclosed \$2.25 for another of your Microscopes. Direct to Henry V. Space, White House, P. O., Hunterdon Co., New-Jersey.

GREAT DISCOVERY.

An adhesive preparation, that is insoluble in Water or Oil and that will stick Patches and Linings to Boots and Shoes sufficiently strong without stitching. It will also mend broken Furniture, Crockery, Toys, and all articles of Household use effectually.

T. HARDY, 208 Broadway.

Roe's Patent Premium Cheese Vat, AND

IMPROVED HEATER.

Patented Dec. 12, 1854, June 22, 1858, May 27, 1862, Jan. 27, 1863.
This most convenient and simple Cheese Vat has been in use more than nine years. Several thousand have been sold, and their reputation is well known in all the great dairy sections of the country.

It has been diligently improved, to embrace every convenience wanted by the dairyman, and to make it simple, cheap, and durable.

We call attention to the improvements made within the last two or three years, for regulating the heating of the milk and scalding the curd, and for supplying hot water, and the very simple and perfect arrangement, by which these are accomplished.

Some new improvements have been added the present season. One of which is a measure or scale, to show the number of gallons of milk in the vat. This is one of those little but valuable improvements, which shows the manufacturer is alive to the interests and wants of his customers.

We pack them to go any distance with safety.
Dairymen in any part of the country, by ordering of us, will get all the improvements and conveniences for cheese making, that are known and in use in the great dairying counties of New-York and Ohio.

Roe's Patent EXPANSION CHEESE HOOP. We sold a large number of these hoops the past season, and learn the dairymen are well pleased with them. A single hoop makes five sizes, and expands to lift off the cheese. For further particulars send for circular.

ROE & BLAIR,
Madison, Lake Co., Ohio.

WORCESTER'S Series of Dictionaries.

THE STANDARD DICTIONARIES OF THE
ENGLISH LANGUAGE.

100,000 BARRELS

OF THE

LODI MANUFACTURING COMPANY'S

POUDRETTE,

FOR SALE BY

JAMES T. FOSTER,

66 COURTLANDT-ST.,

NEW-YORK.

In lots to suit purchasers. This Company have the largest capital and factory of the kind in the world, and possess the best facilities for manufacturing the night soil of New-York City, for which they have the exclusive contract, into a dry, inodorous, but powerful manure—superior to any other fertilizer in market, taking cost and YIELD into consideration. Price \$1.60 per barrel, free from cartage, for any quantity over 7 barrels—or only \$16 per ton.

✓ Beware of spurious imitations, put up in barrels to resemble this Company's brand.

Attention is called to the following letter from a farmer

FARMINGTON, N. H., OCTOBER 9, 1862.

JAMES R. DEY, Esq., President Lodi Manufacturing Co.

For several years past I have used as a fertilizer, the Lodi Manufacturing Co.'s Poudrette. I commenced in 1859. I then had a tenant carrying on my farm upon shares. He agreed to use such artificial means as I should furnish free of expense to him, but he had but little faith in anything but barn-yard manure. I purchased some Poudrette. He took it from the freight-house; opened it; came to me with eyes wide open, and said, "YOU HAVE GOT CHEATED, THIS STUFF IS NOTHING BUT DIRT." I told him, "I supposed I had; it was nothing new: I was in the habit of getting cheated, but as it cost him nothing, I wanted him to use it."

We had a piece of poor, sandy loam land, which he planted with potatoes, without manure. He put Poudrette in the hills eight rows, then omitted eight rows, and then put lime in the hill, as he had a mind to try that.

The result was, that where the Poudrette was put, the potatoes came up three or four days before the others. The tops were twice the size during the season, and at harvesting we measured two lots of each, one of which the Poudrette gave twice the quantity of potatoes, and the other in the proportion of five to three.

The lime had no perceptible effect.

We had a piece of corn land, sandy loam, (my tillage land is sandy and gravelly loam,) the corn had a liberal dressing, say ten cords of barn dung to the acre, spread upon grass land, and put in the fall before the balance in the spring. The tenant prepared a compost to put in the hill, a mixture of night soil, hog manure and loam well mixed, several times shoveled over, and well incorporated together. This was put in the hill. In eight rows through the middle of the piece, this was omitted and Poudrette was substituted instead. The result was, the Poudrette brought the corn up sooner, of a better color, and at the end of two weeks after it came up, nearly twice as large, and it maintained it a head and shoulder above the other during the season. At harvesting, we measured the corn, and where we got five bushels with the compost, we had six bushels with the Poudrette.

This satisfied me, and convinced my unbelieving tenant that it was something besides dirt. I have used it with water ever since, and shall continue to do so, as long as it maintains its character, and is furnished at reasonable prices. We sometimes think we save an entire crop of corn by the use of Poudrette, in case of early frost, as it brings the crop to maturity at least a week earlier.

There has been an increasing demand here since it has been introduced, and from my own observation, and the information of others, I think it does as well on upland soils, as upon sandy loam. I have not been so particular since my first experiment, but every year I left a few rows so as to be sure that it maintains its character. The present year there is a very marked difference in the appearance of a few rows left without the Poudrette, in a piece of corn not yet harvested. The appearance of your Poudrette to one not accustomed to it, is not very flattering. I will relate an anecdote on this point. In 1860 I prevailed upon a neighbor to try a couple of barrels, for which, I think, he paid me \$4.20. He informed me afterwards, that he took it into his field all alone, and opened it; said he, I said to myself, if some one will come along and give me a dollar, he shall have both barrels. No one coming along, he tried it, and has used it every season since, and thinks very highly of its fertilizing qualities. Some of my neighbors have said to me, that they thought it had been worth to them \$5 per barrel. I have used other fertilizers, such as Guano, Superphosphate, &c., most of which are beneficial, but none come fairly up to the Poudrette. One particular advantage Poudrette has over other fertilizers is, that the smell is not offensive, and it will not kill the seed.

And again, it is not so expensive. My method is, to put it in the hill with the seed. A quart by measure is ample for ten hills, at which rate a barrel will manure a thousand hills. I have known it to do well when a less quantity was used. I think nothing else should be put with it. It is a light matter to put it in the hill with the hand, as a person can drop it faster than a boy can drop corn. And it does not require the large hole necessary to put in dung or compost, and is a protection against the wire worm.

Respectfully yours,
GEO. L. WHITEHOUSE.

The Company's pamphlet, containing directions for use and other valuable information, will be sent free to any one applying for the same. Address

J. T. FOSTER,

GOOD GRAPES!

First-rate Vines, well rooted, of the two sorts now conceded to be among the best, if not the very best

FOR

general culture throughout the country. They will be sent by mail, safely packed, and post-paid, on terms that will put it in the power of almost

EVERYBODY,

now a subscriber, to secure for their homesteads one, three, five, ten, or more vines of each sort. (See terms below.) Those wanting large supplies for vineyard culture or otherwise, will of course consult the advertising pages; we have none to sell. Our aim is to enable those wanting a few vines as a beginning, to get them without much trouble, and with no expense. We have had specially grown and selected a very choice stock of vines, which we now propose to distribute only

AS PREMIUMS

to those securing subscribers to the *American Agriculturist*, on and after March 1st, on the terms named below, which can not be varied from. Surely any one can readily secure two or more subscribers for a paper like the *Agriculturist*, which is still supplied at the low price of \$1 a year, notwithstanding the great advance in cost of printing paper, etc.—Our vines are of the two best sorts, viz.:

Delaware and Concord.

The **Delaware** is almost universally conceded to be the best flavored grape for eating and for wine making. Taking into account all its good qualities, it is placed highest on the list in many parts of the country. The scarcity and high price of the vines have prevented their general diffusion. (Less than three years ago we paid \$3 each for our first stock of vines, and very small ones at that.)

The **Concord** is a very early grape, adapting it to cultivation much further north than the *Isabella* and most others. It is exceedingly productive and vigorous, and thrives even under neglect. It has been thoroughly tested, East and West, and though not, in the opinion of many, equal in flavor to the *Delaware*, it is pronounced *very good* by all. For general, *careless* culture, under all circumstances, we place the *Concord* first on the list. Many others put the *Delaware* far before it. (See report of the Fruit Growers' Meeting, on pages 82-3.) Our advice therefore is, that all who can do so should get one or more vines of *each* variety, and multiply the kind that proves to be best suited to their individual locations, soils, and preferences.

Our successful experience in packing and sending out 40,000 Strawberry plants by mail, with not half a dozen cases of failure, has established the practicability of sending *grape vines* in the same manner, with scarcely a fear of loss. We therefore

offer to send these Grape Vines on the following

Conditions:—On and after March 1st (not before), to those sending Subscribers to the *American Agriculturist* for Volume XXII. (1863) at One Dollar each, we will forward, securely packed and post-paid:

For **Two** Subscribers at \$1 each, **1** Vine.
For **Five** Subscribers at \$1 each, **3** Vines.
For **Eight** Subscribers at \$1 each, **5** Vines.
For **Ten** Subscribers at \$1 each, **8** Vines.
For **Fifteen** Subscribers at \$1 each, **15** Vines.

And for over fifteen subscribers, one vine for each name. We specially request that the names of any club for the vines be all sent at the same time.

Those sending for premium vines can make their own choice; if for one vine, which kind; if for two or more, what number of each, and give in full the Post Office address to which they are to be sent.

N. B.—1. The above premiums are *only* for subscribers sent in on or after March 1st, and will only continue open so long as our supply lasts, as it is impossible to add to our present good stock. Probably the supply will hold out through the month of March, and perhaps through part of April, but not certainly.

2. These premiums are special; no other premiums of any kind will be paid on names sent for these vines.

3. The mailing of the vines will commence on or before March 15th, if the season admit, and continue until the middle of April or later, according to the locality to which they are to be sent. To all who apply early enough, a Circular Letter will be sent out about a week in advance, stating the time the plants will be mailed to them. The Circular will also give directions for the treatment of the vines, with hints on culture, etc. The plants going furthest South, will of course be sent first, and those furthest North the latest; but every application will be entered in order, as soon as it comes to hand, so that no one will be unsupplied, who applies before the entire stock of vines is exhausted.

It will of course be a pleasure, as well as for our interest in the future, to have every vine a *good one*, put up carefully and in the best manner, and to have it receive such care and attention as to make it give entire satisfaction. As stated above, we have within a year past mailed 40,000 strawberry plants, and have not heard of half a dozen cases of failure or dissatisfaction. We hope for equally good success with the Grape Vines.

Special to Subscribers in Canada, and on the Pacific Coast.—There will be considerable risk in sending vines to the Pacific Coast after April 1st. The practice of some of the Postmasters in the Canadas and other British Provinces, of charging 20 cents an ounce, after the United States postage is prepaid, will prohibit sending these vines there, except when they can be sent to a United States Post-Office near the Line, or be sent by express. When eight or more are sent together, they can frequently go by express. We do not advise planting the *Delaware* in New-Brunswick, Nova Scotia, Lower Canada, or in Upper Canada, except south of Lake Ontario. The *Concord* will often thrive further North; and in favorable locations, the *Delaware* also.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE,

(For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents. Postage anywhere in the United States and Territories must be paid by the subscriber, and is only six cents a year, if paid in advance at the office where it is received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M.,
EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.
Published both in English and German.

\$1.00 PER ANNUM, IN ADVANCE
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 128.

VOLUME XXII—No. 4.

NEW-YORK, APRIL, 1863.

NEW SERIES—No. 195.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

The showers of April melt the icy fetters which have bound the northern streams, and they sing their hymn of freedom as they run along. The opening of an American Spring is a very matter of fact season. We have few of the flowers which have had the charm of English poetry added to their own loveliness. The Snowdrop does not bloom through our melting snows, nor have we many spring flowers that have been widely celebrated in song. The *Epi-gaea*—the fragrant and modest May Flower of the Pilgrims—did it only grow all over the country might well be taken as our emblematic Spring Flower, but this is found in comparatively few localities. Our most common harbinger of Spring bears the unseemly name of Skunk Cabbage. This with its curiously shaped and mottled horns which are lifted up in the swamps, is the forerunner of the great floral procession which will soon come crowding on. Showers and sunshine in fitful alternation are the characteristics of April. Under their influence the dull pastures brighten into a tender green, and the sombre hue of the woodlands is enlivened by the red of the maple buds, and the warm gray of the poplar tassels. Nature begins to paint the great landscape, and the farmer, did he but know it, is an artist working with nature to help make up the picture. In plowing the fields he is preparing the canvas on which the waving grain and ripening corn shall paint gorgeous and ever-changing colors.

Let us stop here upon the threshold of spring work and consider if the plans formed during the season of rest, have included all that may be accomplished. The main work of the farmer has been laid out and the labor for that must be done. Having provided for the staple crops, is there not some other spring work for which

time can be spared, and which will add much to the comfort and attractiveness of the homestead? In the Autumn we look upon the orchard with its ripening fruit, with great interest, but we are very apt to forget it in the Spring. In spite of neglect the generous trees still yield fruit, which might be increased both in quantity and quality, by a little extra care. If the orchard bears good fruit it may be made to bear better by a coat of thorough manuring now, and judicious pruning at a late season. If the trees are still vigorous, "natural" ones which bear fruit fit for cider only, now is the time to renew them by grafting. If they are old and have suffered from long neglect, now is the time to plant a new orchard to replace them. Last year established the value of orchards. It was one of unprecedented plenty, yet, in most places, good fruit brought remunerative prices, and orchardists are extending their plantations. An orchard of well selected trees will be a great comfort in one's declining years, will be an excellent inheritance to leave children, and, if the homestead should have to be sold, will add to its value an amount that will pay well for the investment.

Another thing that should claim attention is the front yard, or approach to the house. A home-like look can, with a little pains, be given to a very rude dwelling. It is not boards and brick and mortar alone that make an attractive home; it is the manner in which they are put together. Every one, no matter how poor, has certain materials at his disposal, and the character of his home will depend upon the way in which these are used. In the first place, let the front-yard be neat, and if there is neither time nor taste for adornment with flowers and shrubs, have a smooth grass plot with here and there an elm or maple, or other forest tree. We have seen a climbing rose give to a log house an air of rural beauty which is quite wanting in the bleak, staring white houses that many a wealthy farmer builds. Were farmers' dwellings made more attractive both within and without, their sons would be much less willing to leave them.

Work for the Farm, Household, etc.

Accounts—In the haste to commence plowing and sowing, other important interests should not be overlooked. A successful cultivator must be also a man of good business habits; observant of markets, and ready to improve the favorable moment for either buying or selling. Keeping accounts will add to the thrift, and give more certainty to all operations.

Let every transaction of purchase and sale, all contracts, terms made with hired help, time of their commencing work, amount of outlay and return for each field, animal, etc., be plainly noted, for reference. A fairly kept book is better evidence in a court of law than a treacherous memory, or an interested witness.

Barley has proved a profitable crop in many

localities. Sow Spring variety on rich and well pulverized soil, $2\frac{1}{2}$ to 3 bushels per acre. Smut will be prevented, and growth hastened, by soaking the seed 24 hours in a weak solution of blue vitriol and then rolling it in air-slaked lime. Moistening with tar water and rolling in lime, answers a similar purpose. It should not lie long after being prepared, or it will heat.

Birds.—Prepare houses for martin and wren in the vicinity of the dwelling, and allow swallows access to the barn. They are a very efficient police against destructive insects. Tame pigeons feed upon grain, and are not cleanly.

Bones.—Save all found upon, or brought upon the premises, and lay in a large stock, if they can be procured cheaply. They are better than any "patent" manures. Break them with a sledge hammer, and put them freely in the soil around fruit trees. For immediate use upon annual crops, they need to be dissolved in a wooden hooped barrel, in one part of sulphuric acid and two or three parts of water. They need four or five weeks time. The fluid is to be poured off and mixed with a large quantity of muck. Some recommend to moisten them with the acid and then bury them in a heap of horse manure, where they will soften.

Buildings.—Lose no time in finishing such as will be needed for shelter or storing produce. Clean out all rubbish from barns, stables, and sheds, and add all suitable materials to the compost heaps. Whitewash cattle stalls, poultry houses and roosts, and the insides of other out-buildings. Keep all in repair. A good coat of paint where needed will more than repay its cost in preserving woodwork. It is better applied now than later in the season. Trellises for training vines to buildings are preferable to fastening the plants directly upon the boards.

Cabbages.—Those raised in hot-beds for earliest marketing, may be transplanted in favorable weather. Early York is a favorite field cabbage for market. Set in rows 2 by $2\frac{1}{2}$ feet.

Calves.—Raise enough of the best to keep the farm fully stocked. Teach them to drink when one or two days old. After the first week their food may be gradually changed from new to skim milk, and a few weeks later to gruel of shorts, rye, oat or barley meal. A little wheat flour boiled in milk will relieve the scours. Keep their pens dry and clean.

Carrots deserve more extended culture as a field crop. They are of high value for feeding horses, cattle, and sheep, in Winter. Sow on highly manured, mellow, deep soil, free from weeds, in drills 14 inches apart. An acre requires about 2 lbs. of seed. It should be tested by sprouting before sowing; it is often poor.

Cattle, both young and old, need an extra relish of roots, if at hand, or grain, to keep them in condition as Spring advances. Restrain them from the pasture until a fair bite of grass is

grown, otherwise their appetite for hay will diminish, before they can gather enough to keep them in flesh. Deal liberally with working oxen; an occasional feed of potatoes will be beneficial, with a regular allowance of corn meal or shorts. Give roomy stalls to cows about calving, and watch, to render them assistance if needed. In breaking heifers to milk, avoid teaching them to kick by roughly handling their teats when sore. Keep these well oiled, and treat them gently at all times.

Cellars.—Clean out and whitewash at once, if not already done. Windows of fine wire gauze, millinet, or "mosquito cloth," are useful to admit air and exclude insects. If milk be kept there, it should be in an apartment separate from the general store room. Cement the floors, or lay plank flooring wherever it is necessary to walk.

Clover is an important crop. In no better way can a soil be fertilized than by turning under a heavy growth of it. The first of this month is a good time to scatter seed over old meadows and pastures, and especially on winter grain fields. Choose the first still morning, when the ground is full of little frost cracks, and sow seed liberally with or without herds-grass seed—with it if designed for a meadow or pasture for two or three years. The seed falls into the frost openings, and is finely covered in thawing. We have seldom failed of a good "catch" by this method.

Corn.—Good seed, and either good soil or plenty of manure, are the essentials. Corn is one of the seeds most readily injured by dampness or heating—in the shock or crib. It is always best to test an average sample selected from the whole seed in advance, by sprouting in warm soil. It is much better to do this than to risk the loss of a crop, or of many hills. The seed is the least part of the expense. Corn is a gross feeder, and revels in plenty of manure of any kind. It is a sun plant, and not a water one. *Rich land*, warm and dry—drained if at all needed, is what fills the corn crib—and the purse. A heavy sod turned under is a good place for corn roots to revel in.

Cranberries have almost always brought a high price, and are likely to. Many a useless swamp might be turned into a cranberry silver mine, with proper skill. We have given considerable information on the mode of doing it, in previous volumes. Eastwood's little work (costing 50 cents), gives some information on this topic, and is the only book on the subject we know of.

Draining.—"It pays," is the testimony of hundreds of our old readers who followed our earnest advice and suggestions years ago. While waiting for sun and wind to dry out wet land, lay plans to prevent such delays in future, and execute these plans at the earliest practicable moment. Air is essential to roots growing in a soil. Air and water can not both be there at once. Warmth is equally necessary, but rapid or slow evaporation of water from the surface is like an ice bath.

Fences.—A rail was thrown down in Winter; an ox saw it, and went over, leading his companions; they trampled down in a night ten thousand square feet of surface, and half spoiled a dozen or twenty young fruit trees. Enough said.

Grain Fields.—A single animal will soon tramp out plants that would yield a bushel. See page 38 (February). If plants are much heaved by frost, a roller will often benefit them, if used where the ground will not be injured by the team. Fill up the bare spots by harrowing or hoeing in spring-wheat—better have a crop of mixed wheat on the ready prepared ground, than a crop of weeds. Carefully clean the dead furrows, and outlets of under-drains; a small amount of back water may kill out a bushel of grain, which two minutes time would save.

Grass Seed.—See on Clover. Grass seed may be sown at the last harrowing in of oats or other spring grain. The lighter the covering the better.

Hedges.—It is high time to set Osage Orange plants, for at any point where they will flourish, the ground is now ready to work. We should not set

them north of 40°, as a general rule. Let somebody else test the White Willow. Buckthorn will answer in many northern localities. Clean up the useless hedge rows along the fences; they are nurseries of foul weeds, and vermin.

Hogs will probably be in better demand next Autumn, than during the past year, and the pigs should be cared for. Good food to the sows will reappear in the sucking pigs and produce earlier and more rapid development.

Horses.—Inure them to hard work, gradually. Have a merciful harness; a hard spot or badly adjusted draught may give them constant pain, and consequent loss of flesh, and produce a serious galling or sore. More work; more strengthening grain. Washing off mud and sand from the feet and rubbing down at night, will give them comfort and vigor, and may save scratches or othersores. Mares near foaling can not do hard work and bear good progeny: a hard day's drive may take \$10 from the value of a colt.

Manures.—Don't leave any to "waste its sweetness in the desert air," while rotting all Summer in the barn-yard corners, in the pig stys or hen roosts, or in the privies. Every shovelful put under or around crops and trees will reappear greatly multiplied in the grain bin, corn crib, or fruit cellar, before the season is over. No manufactured fertilizer purchased can equal the barn-produced material. After all this is used, it will do to try genuine Peruvian guano, superphosphate made of *unburned* bones and not mixed with cheap matters, and a few other honestly made fertilizers made up principally of animal matters.

Meadows.—It is easier and cheaper to pick up a stone now, than to grind a scythe in haying time; to remove bushes and stubs now than to mend scythe snaths then. A roller settles the frost-heaved roots, and sinks the hummocks and small stones. Fill up the bare spots by sowing seed. Cattle droppings in heaps, if scattered with a long handled mallet, will fertilize several square feet instead of spoiling one. Fine manure, or ashes, or lime, spread broadcast as a top-dressing, will show itself in the hay mow, after (not) many days.

Oats are relatively the highest priced grain in our market—75 to 83 cents a bushel just now. Where the insect is not feared, they are worth looking after. The earlier they can be sown the better. They like good soil but not too much rich manure, or the straw will grow rank and fall.

Onions often pay well as a field crop. Any one cultivating them will find it well worth while to consult the lengthy, full directions given by 17 practical men in our onion book, which costs but two dimes. See advertisement on page 127.

Pastures.—The young grass shoots that would hardly make a bite for an animal now, will, after a few weeks growth, afford several mouthfuls of good nourishing forage. *Erigo*—keep animals off from the pasture until well started. Sheep gnaw so closely as to give the grass no chance to start. Fertilize and fill up pastures the same as meadows.

Plowing.—See page 112. Remember that all the soil below you is *yours*, and appropriate a little more of it every year. Too much of the new soil brought up at one time may injure the whole for the first crop, though not afterwards.

Potatoes.—Plant early on good, mellow clean soil. Coarse, or thoroughly rotted manure is best; fermenting manure is not always safe. Ashes or lime is generally useful, in the hill or whole soil.

Poultry.—More rations, more eggs. Fresh meat while insects are wanting, is the basis of eggs. Ashes or lime to roll in, helps them to keep off insects. Greasing the roosting poles smothers the insects on them.

Roads on the Farm.—A stone removed, or a root pulled up, may save a broken wagon or harness, and perhaps a balky horse. We find coal ashes and cinders make the hardest and best walks and public street crossings without raising high ridges.

Rye.—The same remarks apply to winter rye as to wheat. We are unable to say much about spring rye, and would like to hear from those who can.

Sheep were never before in greater demand, or at higher prices. Every lamb will be worth saving and nursing. Take good care of the ewes; shelter from cold and rains, and separate them from the rest of the flock. Keep them in good heart; feed sparingly, if at all, with grain; they should be in good health, but not fat. Tag locks and filth should be removed from their nadders and elsewhere.

Sorghum.—Prepare the soil the same as for corn, and plant as early as the ground and season will admit, covering very lightly. We prefer 3½ feet drills, the seed sown thickly, and when well started thin out to 10 or 12 inches apart in the row, leaving the best stalks.

Tobacco.—See pages 108 and 104.

Tools.—We can not too often impress the fact, that two men with first-rate implements will do as much as three men with poor ones, while the difference in cost is not great. To be short of good implements is the worst economy, especially in these times of scarcity of help, and high wages.

Trees add to the beauty, comfort, and saleable value of a farm. A purchaser will pay much more for a farm with a few well arranged trees; it looks better to him, though he may not notice why. Fruit trees are of course doubly valuable.

Wheat.—See grain fields above. Spring wheat will come in well to fill the bins and take to market in Autumn. Sow at the earliest date the ground will do to work. After frosts will seldom injure it.

Orchard and Nursery.

This will be a busy time with both the seller and the purchaser of trees. The nurseryman will now experience the utility of preparatory work. If a good stock of trees was heeled in last Fall, in anticipation of the Spring sales, and if labels and packing materials are at hand, a large amount of orders can be rapidly dispatched. The conscientious nurseryman will never send out a badly-grown plant or one about which there is any doubt as to the name, nor will he substitute a variety which he has for one which is not in stock. To those who buy trees we say, deal directly with the nurseryman, and do not buy of traveling tree-peddlars. Consider that an orchard is generally planted for a life-time, and a little care now will save much future vexation. In the first place, find out what varieties of fruit have done well and are most salable in your locality, and make the main planting of such sorts. Doubtful and fancy kinds can be sparingly planted by way of experiment. Having determined what to plant, send the order directly to the nearest reliable nurseryman. If you know of none, look over our advertisements. It will be better to pay the cost of freight from a distance, than to plant unreliable trees if they were furnished without cost. If not ready to set out the trees as soon as they are received, dig a trench large enough to hold the roots, and set them in as close as they will stand, and cover the roots well with earth. Should trees become shriveled from drying, dig a trench and bury the whole, branches and all. In a few days they may be taken out plump and bright.

Apple Trees should be planted early. Manure well and thoroughly plow the soil intended for the orchard. Stake the trees as soon as they are planted. Old trees should be cleansed as directed in basket note on page 103, and have a dressing of manure and ashes spaded in about the roots. See list of varieties adopted by the Fruit-Growers' Meeting, on page 115.

Drainage.—Except in a naturally dry subsoil, drains should be laid in the orchard. Stone sewers or large tiles should be used, and laid at the depth of 3, and better 4, feet, and near enough to remove all water standing in the soil.

Grafting may be done this month, and even later. Cions should be secured before vegetation starts.

The same care should be exercised in selecting cions as in purchasing trees. Merely grafting a tree does not, as many suppose, improve it, unless the graft is of a good kind. Root-grafts may be planted in the nursery as soon as ground is ready.

Insects.—The war on these should never cease. Crush the eggs wherever found, and kill every moth, no matter how beautiful and innocent it may appear.

Manure pays as well in the orchard as anywhere. Some varieties which will not bear at all if neglected, are fruitful and profitable if properly manured. Put it into a considerable area where new trees are to be planted, and on the surface around those already growing.

Pear Trees.—For orchard culture the best growers advise standards; that is, the pear grafted on pear stock, and not on quince. There is no danger that the supply of late pears will equal the demand. See note on page 116, and list of varieties on page 17 of January *Agriculturist*.

Seeds of fruit and ornamental trees should be planted as soon as the ground is ready. These should be sown in drills in good mellow soil.

Stocks.—Seedling stocks taken up last Autumn should be got into the ground. If neglected then, take up as soon as the ground is thawed, and cut back the root and top.

Pruning.—Consult last month's Calendar.

Kitchen Garden.

When the Calendar for March was prepared, there was every prospect of an early Spring—much more so than now, as a month later we make up these directions for April. The ground is frozen, and we have more snow than during February. Still, before this paper reaches the readers, the spell of Winter will perhaps be broken, and the weather admit of active operations in the garden. Nothing is to be gained by "hurrying the season;" the ground must have time to thaw, settle, and become warm, and this will take place much earlier if the garden has been properly drained. In many localities, especially at the North, the suggestions for last month will be appropriate now, while further South, and along the sea-shore, much other work may be done. To those who have a good garden, nothing need be said upon its importance. To those who have not given sufficient attention to this valuable part of the homestead, we would say, it will *pay* to make one. A good warm, rich soil is best, but if that be not found near the dwelling, almost any soil can be brought into good condition by draining, deep plowing, and *plenty of manure*. We know that the garden is almost always the most profitable portion of the farm. Keep a careful debt-and-credit account with it, crediting every item taken off at a fair valuation, and our statements will be proved. Should there be a slight deficit in the course of two or three years, it will be more than made up by the pleasure given. Have a good garden, even though it diminish the staple field crops by a few bushels. A wealthy farmer friend of ours always has early and choice vegetables upon his table, but to save trouble, he buys them in the market of a neighboring city. This may do for him, and others of like means, but not for the great mass. But every one may, with a little exertion, have most luxuries of the garden without going to market. It may be owing somewhat to imagination, but we always think the vegetables of our own raising are better than any that can be bought.

A Hot-bed or Cold-Frame Substitute.—In these hints we often refer to hot-beds and cold frames,—the former a glass-covered box with a bed of warm, fermenting manure under the plants; the latter the glass covered box without the fermenting manure. Their construction has often been described in the *Agriculturist*, and they are so cheaply made, so easily managed, and so convenient, that they may well find a place in most gardens. But when they cannot be had, other methods may be adopted

to secure early plants. Small earthen pots are the best, but one of the cheapest is the use of sods. Cut up good green turf three or four inches deep, and divide it into many little squares with a knife or spade. Pack these pieces closely together, bottom side up, in boxes, or on boards, and plant in the centre of each piece, one or more seeds, of *any* plant desired early—vegetable or flower—corn, peas, tomatoes, melons, cabbages, etc. Whole or cut potatoes may also be put in. Set in a warm place, as on the south side of the barn, house, or shed, but carry them to the cellar or a warm room, if a cold night or day occur. The more sunshine they have the better. The only further care needed will be to always keep the sods moist, *not wet*. This may be done by wetting on the under side along the bottom boards, or by occasional light syringing or sprinkling from above, as needed. The seeds will start and get two or three weeks' growth—a clear gain of so much time. When the soil and season admit, separate the pieces, and set them out in hills or drills, as required, putting the earth well around them. The plants will grow right on, all the better for having the sod decaying around the roots.

Artichokes.—Uncover, and if desired to increase the bed, plant out suckers from old plants, in well-prepared beds. This is not much cultivated, however, and we look upon it as rather a fancy vegetable, which costs more than it comes to.

Asparagus.—This is worth far more than it costs. Rake off the coarser part of the winter covering of manure, and fork the finer portion into the soil, taking care not to injure the crowns. Water with refuse brine, or apply salt. See directions on forcing in March Calendar. Sow seed for new plantations in drills one foot apart. New beds may be made by planting out two-year-old roots. Lay the plot off in beds 4 feet wide, with convenient alleys between. The ground cannot be made too rich or worked too deeply. It is high culture rather than any particular variety that makes large asparagus. Three rows, one foot apart, may be put on a 4-foot bed, with the plants one foot apart in the rows. Put the crowns of the plant at least 4 inches below the surface. Many otherwise good beds are ruined by planting too near the surface.

Beans.—Should not be planted until all danger of frost is past. In some places Early Valentines and Six Weeks may be planted late in the month.

Bean-Poles and Pea-Brush.—These should have been already secured, but if it has been neglected get a supply at once. Nothing looks more unsightly than peas stuck with brush cut after the leaves have started.

Beets.—Sow the Early Bassano as soon as the frost is out of the ground. The seed may be sprouted by soaking over night in warm water; then pour off the water and keep in a covered vessel in a warm place. It is well to dry the seed off before sowing, with plaster if you have it. In sprouting these and all other seeds, the growth should not be allowed to proceed too far, for if the little root be broken off, as it is apt to be in sowing, the germ will perish. As soon as it breaks the seed-coat and appears, the seed should be sown. What passes for the seed of the beet is really a kind of woody cup containing several seeds. If all grow, we have a number of plants very close together. A correspondent suggests to break up the seeds before planting; he finds it to be a saving of seed, and renders future thinning much easier. We have never tried it, but give the suggestion for those who wish to experiment. The seed may be broken by carefully rolling between two boards. Sow in drills 18 inches apart.

Broccoli.—Treat like cauliflower.

Cabbage.—Sow in hot-beds, if not already done, or in sods as above. Transplant from hot-beds as soon as the season will allow. Early York and Sugar-Loaf are still among the best early sorts, and the excellent Winningstadt comes on soon after them. At the last of the month the sowing for a late crop may be made in the open ground.

Carrots.—Sow the Early Horn in rich, deep soil, in drills 1 foot or 15 inches apart.

Cauliflower.—Early plants in the hot-bed may now be potted off or pricked out in a cold frame, if they are getting large, and the season will not permit their being set in the open ground. They will be none the worse for a second transplanting. In planting out, recollect that the ground can hardly be made too rich.

Celery.—The great difficulty with this crop is to get the seeds started, for they are very slow in germinating. They may be sown on a warm border or in a cold frame. A friend of ours, who never fails of getting a crop, piles the brush and rubbish of the garden upon the bed and burns it, and then rakes the ashes in with the soil, and sows the seed when the bed is cool. No doubt this burning over the bed may be advantageously practised with many seeds that are slow to start. The seeds of weeds are killed, and the ashes act as a fertilizer.

Cold Frames.—These may still be advantageously used, to start tender seedlings. Those in which the plants are already up, should have the sash removed every fine day.

Cress or Pepper-Grass.—Sow early in rows 6 inches apart. Sprinkle the plants with ashes to keep off insects.

Cucumbers.—Nothing is gained by planting too early in the open air. Some for an early crop may be started in the hot-beds or on sods. The Early Russian is a favorite sort for an early crop.

Drain wherever needed. There are but few gardens that will not pay well for draining. This improves the texture, admits air and warms the soil, making it much earlier. A drain or two costing but little, will sometimes double the yield of a whole garden, and bring everything forward earlier.

Egg Plants.—These cannot be forwarded too soon. If not already growing in the hot-bed, they should be sown at once. Pot off the plants which are large enough. The Long Purple is the earliest, but the large Purple is most generally cultivated.

Garlic.—Set out the divisions of the bulbs, or cloves as they are called. This is little employed in cooking in this country. Judiciously used in very small quantities, it imparts a most delicious flavor to soups, stews, etc.

Horse Radish.—New beds may be made by planting crowns or pieces of the root. Make the bed where it can remain permanently, as it is almost impossible to eradicate it to make room for another crop. The benefit of liberal manuring will be seen in the increased size of the roots.

Hot-beds.—Give plenty of air to prevent the plants from becoming too delicate. Stir the soil between the rows, which has become hardened by frequent watering. Weed carefully, and thin out the plants where crowded. In many localities the first of this month will be quite early enough to start a hot-bed for plants for the family garden.

Kohl Rabi.—Sow in hot-bed or sods for early, and in the open ground at the last of the month.

Leeks.—Sow in rich soil in rows 15 inches apart.

Lettuce.—Transplant from the hot-bed as soon as the season will allow; sow in hot-beds, or cold frames, or in sods, and in the open ground. There are so many varieties that we are puzzled to make a selection. The Neapolitan Cabbage, the Butter, and the Ice Drumhead, will satisfy every one.

Manure.—There should be a bank of well-decomposed manure always ready to honor all demands. Prepare for liquid manure. A peck more or less of hen-dung in a barrel of water makes a wonderful persuader to vegetation.

Mustard may be sown for salad or greens as soon as the ground is open.

Melons may be started in the same way as cucumbers. Try the White Japan, if possible to procure the seeds. The Jenny Lind is very early and good.

Nasturtiums are useful and ornamental, and very easily grown. They make the best of pickles, and

yield beautiful flowers. Sow in a warm place the last of the month, and give them some support. Pea-brush will do, or, if near a fence, they may run upon strings or wires.

Onions.—Put out Potato and Top onions, and sow seed in rich mellow soil. Avoid the use of manure containing foul seeds. Muck and ashes are excellent for this crop. Some cultivators burn over the bed to destroy the weed-seeds. Use great care to get pure seed. Sow thinly in drills 15 inches apart.

Pursley.—Sow early. It is always a long time in coming up. It is sometimes sown along the margins of beds, for which it is a very pretty edging.

Turnips.—Sow in rich, deep soil, at the last of the month, if the weather admits. A correspondent suggests that those of last year's crop still in the ground have the tops cut off about half an inch: in this way they will keep good until the ground is needed for another crop.

Peas.—See article on page 115, this number.

Peppers.—Sow in hot-bed or sods. The true thick-fleshed squash pepper is the best for pickling.

Radishes.—A light, quick, sandy soil is essential. Unless a radish grows rapidly it is worthless. Sow early, and at intervals for succession. The Turnip-rooted and Olive-shaped are good sorts. Water with liquid manure; use ashes if attacked by insects.

Rhubarb.—Set out whole roots or crowns, as soon as the ground will admit of working. Three feet apart is usually quite near enough to give the leaves room to expand. Make the ground rich with well-rotted manure. Fork in plenty of manure around the old stocks. See Calendar for February. Seed may be sown as early as convenient. All who could not get one or two year-old roots or crowns, have doubtless sent for seed from our distribution. The young seedling plants will require less room the first year, and may be kept in a bed, thinning out, or transplanting as needed to prevent crowding. Note the best and largest plants for after use. Ten to twenty roots are all that will be needed by any ordinary family.

Salsify.—Sow as early as the season will admit. See article on page 84, last month.

Seeds.—Many of these can be profitably raised in the garden, while others may be purchased more cheaply of those who make a business of growing them. Set out all roots which have been saved for seed, as well as seed onions, in a rich spot, and where they can be daily noticed, in order that they may be gathered at the right time.

Squashes.—Summer squashes may be started as directed for cucumbers. Winter sorts should not be planted until the ground is thoroughly warmed.

Sweet Herbs.—There should always be a bed for these humble, yet useful tenants of the garden. The perennial sorts, like lavender, thyme, hyssop, etc., may be propagated by division of the roots. We prefer to start sage from the seed or from cuttings. Summer savory, basil, and sweet marjoram, may be sown when the ground is warm.

Sweet Potatoes.—The roots may be placed in a hot-bed, in order to get sets for planting. In absence of a hot-bed a frame of boards may be placed over a heap of fermenting manure covered with a few inches of earth. The potatoes will soon sprout. The frame should be covered with boards at night and during cold days.

Spinach.—There should be a good supply from the wintered crop. Sow early for succession, in drills a foot apart.

Tomatoes.—Pot off from the hot-beds those that are large enough, and place the pots in a cold frame. See article on page 114. If not done already, start seed in the hot-bed, or in sods.

Tools.—Clean every one before it is put away. If you have never used a spading fork or hayonet hoe, try them and you will not readily give them up. A man with a first-rate hoe or other implement will do twice as much as two men with poor

tools, and the saving of time will often pay in a single day for the greater cost of the former.

Turnips.—Early kinds should be sown.

Winter Cherry or Physalis should be grown as directed for Tomatoes.

Flower Garden and Lawn.

The work here will be mainly that indicated in last month's Calendar. Clearing up, planting shrubbery, and making preparations for the open season, will fully occupy all the time that can be given to this department. New grounds may be laid out, and old ones enlarged or improved. A garden is never finished. Each year presents suggestions towards that perfection which we all take so much pleasure in striving for, but never fully attain.

Annuals.—Asters, Balsams and others may still be sown in hot-beds, or, in absence of this, in a cold frame, or in sods as described under the Kitchen Garden. Those started earlier should be thinned and weeded if they need it, and if large enough they should be put into small pots to be ready to turn out as soon as the season will permit. As a general thing sowing is done in the open air too early.—See article on early sowing on page 115.—Still many hardy annuals can be properly put in as soon as the ground is in working condition. Two years ago we were unable to sow a large assortment of over a hundred varieties of annuals until June 1, and we had better success than in any previous year. As a general rule those annuals which readily spring from seed that is self-sown in Autumn may be put in early. Among these are Petunias, Whitlavia, Portulacaea, Larkspurs, Candy-tuft, Sweet Alyssum, etc.

Bulbs.—Many of these will show flowers this month. In most localities the winter covering may be all removed very soon. Tall-growing sorts, such as Crown Imperials and some of the Hyacinths, will need to be staked, to prevent winds from breaking them down.

Cold Frames and Pits should be opened every mild day, to harden off the plants before they are turned out.

Climbers should be pruned and trained. Plant new ones in appropriate places. The Wistaria is one of the favorite climbers, and will stand the Winter wherever it is not colder than around New-York. In colder localities it may be laid down and covered with earth. For foliage merely, nothing is more beautiful than the Virginia Creeper, sometimes called the American Ivy or Woodbine. It grows everywhere, and can be readily transplanted from the woods. It is not poisonous, as many suppose. The poisonous Ivy has a three-parted leaf, while that of the Virginia Creeper is five-parted.

Edgings.—These are of great importance to the neatness of the garden, and are always a source of trouble. The edgings are very neat, but they are too expensive for most people. Box makes a neat edging, but it must be frequently cut, and needs to be reset every few years: besides, when the Winter is severe it dies out in spots and becomes ragged. Grass edgings are easily obtained, but they require frequent trimming to keep the roots from spreading. Whoever will introduce a neat, hardy, and easily-kept edging plant, will do a good deed. We prefer grass edgings, neatly kept and trimmed. They should be 6 or 8 inches wide. It is best to cut the turf in an old pasture, in strips twice as wide as the edging, as they are more easily transported, and can be divided with the edging-knife or a sharp spade, near the place they are to be laid.

Evergreens are transplanted with best success in May. Norway Spruce and Arbor Vitæ will bear removal earlier. Never let the roots of an evergreen be exposed to drying winds. More attention should be given to broad-leaved evergreens like the Holly, Laurel, Rhododendrons, etc.

Gravel Walks.—Remove all weeds and give a dressing of fresh gravel where needed. In making

new walks, be careful to select gravel that will pack firmly. Coarse river gravel will not answer.

Hedges and Screens may be set out. Buckthorn, Privet, and Hihiseus or "Shrubby Althæa," make good hedges. Arbor Vitæ, Red Cedar, and Norway Spruce, are best for screens.

Lawns.—If there are but few bare spots of moderate size, they may be filled with turf; if large, it will be necessary to sow seed. A top-dressing of fine compost will be beneficial: even coarse manure may be used if the lough stuff is raked off after the rains have washed out the soluble portions. Plaster is a valuable application, on most lawns.

Manure.—If the borders had a dressing in Autumn, it should be forked in. If not, give them a good supply of fine compost. Don't forget that the trees on the lawn will thank you for manure by increased growth and beauty.

Perennials and Biennials.—Set out as early as practicable. See page 117 for a good selection. Hollyhocks and Sweet Williams should have been put out in Autumn; if neglected then, attend to it now. When it becomes warm enough for the main sowing, do not forget to put in seeds in a reserve bed, for a future supply of these plants.

Roses.—Plant out new, and transplant any old needing removal early. For ordinary culture, we prefer only those which bloom freely on their own roots. Many fine kinds are grafted, but they will soon disappoint those who cannot give them extra attention.

Shrubs.—Plant in masses as a rule. Single large growing specimens have a fine effect on the lawn. Have a regard to the winter aspect of the garden, and introduce evergreens where they will appear to good advantage when all other shrubs are bare. Wiegandias, Spiræas, Japan Quince, Lilacs, Flowering Almond, and Plum, should be in every collection. Where it is desirable, increase by divisions of large specimens. The purple-leaved Barberry makes a fine contrast to the green of other shrubs.

Trees.—Plant in every appropriate spot. Study the effect that will be produced, and do not plant a round-headed tree like a maple where a graceful elm would be more pleasing. Every tree has its particular expression, and where much planting is to be done, the advice of a landscape gardener should be taken, or standard works upon the subject should be consulted.

Fruit Garden.

These hints are given under a distinct head because in the best culture vegetables and fruits are grown in separate grounds, but they are equally applicable where circumstances require that both be grown together. In planting fruits of any kind it is important to get good sorts, and this is equally necessary with small fruits as with large. We have already given lists of pears and grapes, and on other pages of the present number will be found lists of other fruits fixed upon by practical growers after a full discussion upon their merits.

Cherries.—Plant standards or dwarfs as early as possible. Most varieties may be dwarfed by budding on the Mahaleb stock, when they form compact bushes suitable for the garden.

Currants.—Old plants need no attention now beyond liberal manuring. Currants are generally left to take care of themselves, but no plant more readily responds to good cultivation. Chip manure is excellent for them, but they will be glad of something better. Rooted cuttings of last year may now be put out where they are to stand, cutting back the last year's growth to three or four buds. Cuttings made in the Fall and Winter should be put out; they should be put two-thirds of their length in the ground, and have all the buds which are buried removed.

Figs.—These are sometimes grown at the North, but they require great care in laying down in Autumn, and even then are killed by a severe Winter.

Uncover as soon as the weather becomes settled.

Gooseberries.—Treat these the same as currants.

Grapes.—No farm or garden should be without this delicious fruit. There are some sorts which will do well without extra care, and others which will well repay for pruning. See reports of the Fruit-Growers' meetings in March number, and articles on page 116. Our special premium of grapes will doubtless be the means of introducing good varieties to many localities. Where there are late frosts it is best to remove the winter covering of earth from the vines, and leave them laying on the ground until all danger of frost has passed, having straw or litter ready to throw over them in case protection is needed. Great care is needed in tying vines up to the trellis after they have started. Fork well-rotted manure into the borders, if not rich.

Pears.—No garden can be complete without a good selection of dwarf pears. They are always the pets of the garden, and well repay the care bestowed on them. See January *Agriculturist*, page 17, for a list of choice varieties. Trees that have been properly grown in the nursery will have but one main stem, and be well furnished with branches, the lowest of which start from near the ground. Before planting out cut back at least one-half of the former season's growth.

Quinces.—Put out cuttings in rich soil. This tree is generally left to have its own way, but it can be made to grow shapely by proper pruning.

Raspberries.—Plant out in rows 4 feet apart, with the plants 3 feet in the row. Uncover those buried for the Winter, and tie up the canes to stakes or trellises. Cut away the canes which fruited last year, if not done before. Fork a good dressing of manure around the roots, if not in good rich soil.

Strawberries.—The mulching of straw applied in Autumn should be parted directly over the plants. New beds may be prepared and planted; make them in good soil, and enrich it with old manure. Make the beds 4 feet wide, with alleys two feet wide between them. Three rows of plants may be put upon a bed of this width. Set them 18 inches apart each way, which will bring the outside rows 6 inches from the edge of the bed. The plants, when taken up, should be prepared for planting by removing all the dead leaves, and shortening the roots about one-third. Spread out the roots evenly, and plant as deeply as can be conveniently done without leaving any soil on the crowns of the plants.

Trellises.—Should be repaired. See page 116 for description of a cheap and neat style of trellis.

Green and Hot-Houses.

Fire heat in the green-house may now be dispensed with during warm days, but will often be needed at night. Keep the house open as much as possible, in order to prepare the plants for removal to the grounds. Hot-houses will need much less fire and more air as the weather grows milder.

Bedding Plants.—The rooted stock should be potted off. Cuttings of *Verbenas*, *Ageratums*, *Petunias*, etc., may still be made.

Bulbs.—The hardy kinds that are out of bloom may be turned into the border.

Callas.—Water freely, and turn to keep them from drawing toward the light.

Camellias.—Those out of flower should be kept in a growing state. Syringe freely and prune into shape. Make cuttings.

Fuschias will need more water as the blooming season approaches. Insert a stock of cuttings.

Grapes.—These are in such different states of forwardness that no particular directions can be given. Those forced early will have the fruit of a size to require thinning. Cut back the laterals above the bunches to three leaves. Syringe with water to which sulphur has been added, to prevent mildew.

Insects increase rapidly, and will soon injure the young growth if not checked. Use whale oil soap, and other preventives, as already recommended.

Inarching may be performed on oranges, lemons, and other shrubby plants.

Pruning.—Head back unshapely and feeble plants, to induce the formation of vigorous shoots.

Seeds of green and hot-house plants may now be sown. Those of tropical countries will need a strong bottom heat. Where there is room sow a few pots with annuals, or even garden vegetables.

Shifting.—Plants needing more room may be repotted. Cut away any diseased roots. Dress with fresh earth those that do not need shifting.

Water freely rapidly-growing plants. Cactuses, aloes, and other succulents need but little water.

Weeds and Moss should be carefully kept down.

Apiary in April.

Strong stocks of bees need little attention now, except to destroy any moths that may have found their way into the enclosure. The moth worms may be found curled up on the floor of the hives on cold mornings, whence they are easily removed on raising the hive.... Clean out all filth, and any clusters of dead bees about the combs. The bees collect pollen, and but very little honey at this season. If the store of honey in any hive has fallen short, put a supply in shallow dishes under the boxes, with shavings or chips in it for the bees to alight on.... When short of home rations at this season, bees are prone to rob others. Watch for unusual excitement towards evening. A strong hive attacked will usually defend itself, especially if the entrance be contracted so that they can meet the intruders one at a time. Weak colonies should be removed at once to a cellar or dark room, until after a few warm days, when the poachers will have turned to honest pursuits. Stop depredations as early as possible; a successful robbery emboldens them to further free-booting.... It is seldom advisable to disturb bees already doing well. If changes are to be made to movable frame hives or otherwise, let it be done now. Look out now for any more hives needed at the swarming season.

Strawberry Exhibition.

AT THE

OFFICE OF THE AMERICAN AGRICULTURIST
\$50 in Prizes.

The Proprietor of the *Agriculturist* invites Strawberry Growers, of this vicinity and elsewhere, to make an exhibition of their choice fruit on Thursday and Friday, June 18th and 19th,* at the American Agriculturist Office; and to give zest to the exhibition, offers the following

PRIZES:

A—For best 25 approved varieties (one quart each).....	\$7
B—Second prize.....	4
C—Third prize.....	2
D—For best dish of market berries (two quarts of one variety.—It will be very desirable to show plants with fruit in addition).....	3
E—For second and third best do. do.....	\$3, \$2
F—For largest three berries of one variety, (weight and size both being considered).....	2
G—For best New Seedling not before exhibited.....	2
H—For Second Best Seedling not before exhibited.....	5
I—For best flavored Strawberries (one quart).....	2
J—For best quart of White Strawberries.....	2
K—For best quart Everbearing.....	2
L—For best quart of Bonte St. Julien.....	1
M—For best quart of La Constante.....	1
N—For best pint of Princesse Frederick William.....	1
O—For best pint of Empress Eugenie.....	1
P—For best pint of Marguerite.....	1
Q—For best quart Fillmore.....	1
R—For best quart Cutter.....	1
S—For best quart of Triomphe de Gand.....	1
T—For best quart Wilson's Albany.....	1
U—For best quart Hooker's Seedling.....	1
V—For best quart Hovey's Seedling.....	1
W—For best quart Victoria.....	1
X—For best quart Jenny Lind.....	1
Y—For best quart Vicomtesse Hericart de Thury.....	1

No sample can compete for more than one prize.

The berries to come in competition for the premiums must be upon the tables as early as 11 A. M. on Thursday June 18th, and each specimen must be correctly labeled. The Awarding Committee will attend to their duties at 12 M.—The exhibition will not open to the public until 2 P. M. When the premiums are awarded, the names, residence, and places of business of the exhibitors will be put upon the specimens, and the prize samples designated.

No Fruit exhibited will be removed before Friday evening without special permit.

The Committee of Award appointed by the Fruit Growers' Meeting, will consist of some of the most noted and reliable judges of fruits in the country.

* Should any peculiarity of the season require a change to be made in the date of holding the exhibition, notice will be given in the June *Agriculturist*.

Small Fruits—Good Varieties.

Since our inside sheet went to press, the N. Y. FRUIT GROWERS' MEETING have finished the discussion, and adopted the following list of small fruits to be recommended for general culture:

APRICOTS.—Dubois' Golden; Peach or Moorpark; and as promising well: D'Oulin.

CHERRIES.—Belic de Choisy; Black Eagle; Coe's Transparent; Elton; Early Richmond; Black Tartarian; Rockport Bigarreau; and May Duke.

CURRANTS.—Large Red Dutch; Versailles; Victoria; White Grape; White Dutch; Cherry; and Black Naples.

GOOSEBERRIES.—Downing's, Houghton's, and Mountain Seedlings.

GRAPES PROMISING WELL.—In addition to the list of those recommended for general culture, and for special localities, (see page 83 of February *Agriculturist*), the following were subsequently selected as the most promising: Creveling; Cuyahoga; and Allen's Hybrid. The list of wine grapes, after considerable discussion, was laid upon the table.

PLUMS.—Green Gage; Coe's Golden Drop; Imperial Gage; Washington, or Bolmar; Smith's Orleans; Jefferson; Lombard; and Yellow Gage.

PEACHES.—For *Free Stones*: Crawford's Early; Crawford's Late; Early York; Bergen's Yellow; George IV; Oldmixon Free; Morris White; Smock's Late; Cool-edge's Favorite; Slump; Smock's Free. For *Cling-stones*: Heath; Large White; and Oldmixon.

NECTARINES.—Downton; Stanwick; Early Newington; and Boston.

RASPBERRIES.—Hornet; Franconia; Brinckle's Orange; Belle de Fontenay; and Doolittle's Black Cap.

QUINCES.—Orange; Rae's Seedling; and Portugal.

STRAWBERRIES: Triomphe de Gand; Bartlett; Wilson's Albany; La Constante; Cutter's Seedling; and Newland's Seedling (also known as the Pyramidal Chili.)

Containing a great variety of items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

The Weather.—The season is very backward. We had March weather in January and February, and are now having February weather in March. At this date, (March 20,) even in this locality, the ground is deeply frozen, and partly covered with snow. Better thus, than to have a cold April and May, if so be that we do not have frosts and snow then. This late cold weather has promoted the filling of ice-houses, and is likely to have a favorable effect on fruit by keeping back the buds.

The New Agricultural Bureau.

We recently spent a few days at Washington, partly to witness the closing proceedings of the Memorable 37th Congress, but mainly to look into the personnel, the working, and the prospects of the new "Department of Agriculture." There is certainly an improvement upon anything we have had for several years past. Hitherto there has been both incapacity and want of integrity. At present we believe there is an earnest desire to do the best possible for the agriculture of the country. Whether there is the needed ability, we shall wait to learn from what is accomplished. We have neither time nor room for further remarks this month.

"Vineland Lands."—We made a hurried visit to this locality, on March 5th, and intended to present a statement of our observations, but the great press upon our columns compels us to defer any further notice of the matter until next month.

"English Wine Plant."—To several inquirers. This is merely a Rhubarb plant such as is common all over the country. One of the best varieties for cooking or "wine", is the Linnaeus, the seed of which we offered freely in our Seed Distribution. The roots are offered in our advertising columns by reliable growers, at \$15 to \$18 per thousand, and there is no necessity for paying \$250 per thousand to traveling agents, for roots no better, if as good. The Ohio parties who are trying to get up an excitement on the subject, are honest enough to say that their "English Wine Plant" is a seedling of the English Rhubarb. We have seen many samples of alcoholic liquids made from the juice of the Rhubarb, but never a real wine. The great stories about its being a "delicious wholesome beverage PURIFYING THE BLOOD....infallible remedy for Dropsical Complaints," etc., will do for an advertisement—on a par we should say with the "sarsaparilla syrups" of the past. Before going into the speculation, better inquire how much of the best rhubarb wine can be actually contracted for with responsible parties, at 50 or 75 cents a gallon, let alone \$2,

Remedy for Foot Rot in Sheep.—A correspondent at Wilmington, Del., gives the following directions for treating this disease. "To 4 ozs. butter of antimony, add $\frac{1}{2}$ oz. of corrosive sublimate. Pare off all the loose parts of the hoof and apply some of the mixture; then tie a rag around the foot. Examine it next day and if any part has escaped, apply again. It is very difficult to eradicate this disease from a flock where a number are affected, as with the greatest care new cases will occasionally occur, and unless the sheep are valuable, the butcher had better have them. [We hardly dare endorse a medicine composed of antimony and corrosive sublimate. It may be safe, however, and if so, would probably be effective.—Ed.]

"Blind Staggers" in Sheep.—N. D. Townsend, Vermilion Co., Ill. From the description of the disease among your flock, we judge it to be "Hydatid on the brain." The Hydatid is a minute parasitic insect, that in some unexplained manner finds its way to the brain, and forms a small sack containing watery fluid, in which it multiplies. These sacs increase in size, press upon the brain and absorb its substance, causing derangement, and ultimate death of the sheep. No certain cure is known. As the disease is most prevalent in weak animals, the preventive is to keep them in good condition. The malady is most frequent in wet marshy districts, and little known upon upland or dry pastures.

Grub in the Head of Sheep.—"Farmer's Son." The grub found in the head of sheep is the larva of a small fly, (*Estrus ovis*). The winged insect is common during the months of July and August. It seeks to enter the nose of the sheep to deposit its eggs. The animals have a great dread of it, and may often be seen standing in a circle holding their heads near the ground, to escape it. From the egg, a small worm is hatched, which makes its way up to some of the cavities opening from the nose, where it remains and feeds upon the mucus secreted by the membranous lining. The following Spring the full grown grub crawls out, and enters the ground, where it changes to a chrysalis and then to a perfect fly. The only difficulty known to be caused by the grub, is an unpleasant irritation to the animal: this may result in inflammation and disease, but no well authenticated instances are on record. A partial preventive is to plow a furrow through the pasture where the sheep may protect their noses. Some shepherds recommend to tar the noses of the animals during the Summer. We know of no cure. If let alone, the worms will leave of themselves in the Spring.

Poisoned Sheep.—Samuel Cone, Berkshire Co., Mass., inquires if wild parsnip is poisonous to sheep, and if so, what is the remedy. He has lost several sheep apparently from eating hay containing the wild parsnip.

Apple Pomace for Feed.—William Hull, Wayne Co., Pa. We have no experience in feeding stock with apple pomace, but should judge it to be of small value. Mixed with plenty of corn meal, it might be of some service. The experiment is worth trying.

Hungarian Grass for Horses.—E. Boyd, Cayuga Co., O. We have seen no account of injury done to horses by the beard of this grass adhering to the coat of the stomach. The seed alone is too hearty food, and liable to induce inflammation. If fed with the straw it is generally thought to be safe, we believe.

Disease Among Poultry.—"J. E. R.," Orange Co., N. Y., writes that many choice fowls have died in that place of what seems to be chicken pox. The head becomes swollen, and sores the size of a pea appear on the combs, gills, etc. The fowls soon become entirely blind, and consequently die of starvation.

To Keep Birds from Corn.—A correspondent at Wilmington, Del., directs to put a bushel of corn into a half hoghead or other convenient vessel, and set it in the sun, or where it will be warmed. Pour over it a half pint of gas tar or a pint of common tar, and mix well until every kernel is smeared. Then stir in ashes, fine lime, or plaster, until the grains are separated, and spread it out to dry. [Without regard to the birds, it is generally well to smear the corn with tar, dissolved in from four to five times its bulk of warm water, and dry it off with fresh slaked lime. This kills smut; the tar is a good fertilizer itself; and the lime fits some of the soil to nourish the young plants. Birds will not eat it, but generally they are not satisfied without pulling up the kernels to find out whether they are tarred or not.—Ed.]

What of the Italian Bee?—Since the excitement attendant upon introducing this variety of the bee into the United States, but little has appeared on the

subject. We have heard of fair success in raising them by a few individuals, but hardly enough to yet advise substituting them for the ordinary kind. A reliable statement of facts, showing their comparative value, from those who have fairly tried the experiment, would be of interest.

Good "Coon Hunting."—E. Haynes, thus describes how he got the *American Agriculturist* for 1863. "I was out of money and did not know how to get any. The thought came that I could make the coons pay for my paper; so I got up at 4 o'clock, one morning in the middle of last December and started out with dog and gun. I got back at 5 $\frac{1}{2}$ o'clock with two coons, being gone just 1 $\frac{1}{2}$ hours. I sold one skin for one dollar, the other a small one, for 63 cents. I got 3 quarts oil out of both coons; sold 1 quart oil for 31 cents; have 2 qts. left worth 62 cents. So you see I made \$2.56 before breakfast. I send for the *Agriculturist*, *American Missionary* and the *Advocate and Guardian*. It pays don't it? [Certainly, such successful hunting pays, at such prices for coon skins; but it is not often that like good fortune is met with. As a rule, hunting hen's nests will prove more successful. Another subscriber says that the eggs and chickens produced by one hen last year, sold for enough to pay for his paper two years; and that the increased product of eggs by 12 hens, from following one hint in his *Agriculturist* about giving them fresh meat scraps, has paid for several years' subscriptions, during the present Winter. It always pays to hunt for good papers.—Ed.]

Crop for Newly Drained Land.—P. Putnam, Washington Co., N. Y. Almost any grain crop will succeed on well-drained land. A plentiful application of lime will be beneficial to ameliorate a sour mucky soil. If in good heart, a crop of potatoes will be likely to succeed, to be followed by rye the next Fall.

Re-seeding Bare Spots.—C. B. Huntington, Craneville, N. J. Give the bare spots in pasture land a thorough dressing with a heavy harrow; sow the seed, roll it in, and top-dress with finely pulverized manure.

Giving Corn a Good Start.—Gideon Archer, Monroe Co., N. Y., writes that he has obtained excellent results with corn by applying a mixture of equal parts of lime, plaster, and ashes, a handful to a hill, before the grain comes up. A vigorous start given to any young plant enables it to make strong and rapid growth.

Binders for Corn.—"L. F.," writes us that corn which has been sown thick for fodder, makes the best binder he has ever used. Strips of the inner Basswood tree are sometimes used for the same purpose.

English Seed Drill.—Wm. Grawcock, Whitely Co., Ind. We know of no implement answering your description, made in this country.

Flax Seed.—This is so high, partly because of the unusual demand for sowing this Spring, and partly because the manner in which a large share of it is cultivated, keeps it in a few hands. In many places the manufacturers of linseed oil furnish the farmers with seed and contract for the whole crop at a certain price. This prevents the growers from benefiting by the present advance.

Cotton in Illinois.—Rev. J. A. Bent, of Hoyleton, Ill., (incorrectly printed in March, as Hazelton,) sends us the following additional note: "Since writing you concerning my attempt at raising cotton, I have made inquiries at places in Southern Illinois, where cotton gins are in operation, and I am convinced that in this part of the State, cotton may be reasonably expected to do better than mine did. I think in our rich soils it should be crowded in the drill to prevent overgrowth of stock, and to hasten maturity. Tennesseans resident here now, with whom I have conversed, think that from 500 to 1200 lbs. of unginned cotton can be raised; or from 150 to 350 lbs. of ginned cotton to the acre.—The people, stimulated by the extraordinary price of cotton, will plant a very large amount in Southern Illinois this year. All the seed is eagerly obtained at the gins. If nothing untoward prevents, you may expect to hear of an unprecedented cotton crop this year. Many are proposing to plant from 1 to 15 acres.

Garnet Chili Potatoes.—P. Putnam, of Putnam Co., N. Y., noticing our remark that this variety became hollow, says that he has not found it to be the case, and he thinks we may have mistaken the Chili Red for the Garnet Chili. The seed we used came directly from Mr. Goodrich, the originator, and was planted the first year on tilled land well manured, and the second year upon old pasture sod without manure. The potatoes were in both instances hollow and unfit for the table, though the yield was very large. We shall be glad to

learn that this is an exceptional case, as the variety seems to have the other qualities desirable in a good field potato.

Beet Sugar in Illinois.—C. H. Thayer, of Livingston Co., informs us that an extensive factory for beet sugar and sorghum is being erected at Chatsworth. The Ill. Central R. R. freight all beets raised along the line of the road free of charge. Preparations are being made for extended planting of the beet, and he promises to advise us of the success.

The Big Beet Beaten.—J. V. Kinney, Somerset Co., N. J., writes that last Summer he raised a beet of the Bassano variety, from seed distributed at the *Agriculturist* Office, which measured three feet in circumference. This beats the beet mentioned in the January number, by ten inches. [How much did it weigh?]

Quantity of Seed to the Acre.—Preston H. Smith. Seeds vary so much in their quality, especially some of the kinds you enumerate, that it is difficult to give precise quantities. There are sown of beets from 2 to 4 lbs; carrots, 1 $\frac{1}{2}$ to 2 lbs.; parsneps, 2 to 4 lbs.; turnips, 1 to 1 $\frac{1}{2}$ lbs.; $\frac{1}{2}$ lb. of cabbage seed should give plants enough for an acre, and enough to replace all destroyed by the cut worm.

Hard Coal Ashes.—Chas. Booth, Worcester Co., Mass. If the soil of the garden is stiff and clayey, coal ashes would be beneficial. Composted with the contents of the privy they would not be as good an absorbent as muck or loam.

Grass for a Name.—T. C. Wells, Kansas. The grass is *Uniola latifolia* or Broad-leaved Spike-grass. It grows wild at the West, and is so beautiful that it is often cultivated in gardens. It is a perennial.

Average Yield of Grain.—A statistical subscriber wishes to know if any one can inform him of the average yield per acre of wheat, corn, rye and oats in the United States, or in any single State or district.

Chenango Strawberry Apple.—The account of this apple, given on the authority of one of our best pomologists, is objected to by another fruit grower of large experience who says: "To my taste it is very nearly 'very good'—ripe in September and continues until the middle and last of October. Flesh tender, juicy, pleasant sub-acid; a very good amateur's fruit, but too tender for carriage to market. This is distinct from the Washington Strawberry."

Sweet and Sour Apple.—"T. H." This is an old variety which becomes unequally flavored. One side of it is slightly different from the other. The stories about producing an apple half sweet and half sour by budding with two half buds of different kinds, is all *bosh*.

Apples in Southern Illinois.—A. R. Rankin, of Crawford Co., Ill., says the following apples have proved good in Southern Indiana, and Illinois, viz.: Rawles Jannet, Belleflower, Rambo, Domine, Golden Gate (very fine,) Newtown Pippin, and Pryor's Red. Fall Pippin, Red Streak and Smokehouse also do well.

Trees from Cuttings.—N. Gilbert, Oswego Co., N. Y. Peach, plum and cherry trees can not be successfully raised from cuttings in this climate. The quince is propagated easily from cuttings planted in a shaded place in the Spring.

Stocks for Dwarf Apples.—J. H. Miller, Pa. Doucin and Paradise stock are propagated by layers. The plant is cut off near the ground so as to induce it to throw out numerous shoots which are allowed to grow one season. The next Spring a mound of earth is heaped up around the shoots, so that the base of each one of them will be covered by at least three inches of earth. The shoots will take root and may be removed from the parent root in the Fall. The stocks can be procured cheaply from the large nursery establishments.

Ashes for Peach Trees.—E. Rex, Crawford Co., Ohio, says that when the trees are large enough to bear, he removes the sod in the Spring so as to lay bare the upper roots, and fills in the space with leached ashes. In the Fall the ashes are removed, and leaf or other vegetable mold put in their place. He says that he finds doing this every other season, preserves the trees in fine condition and prevents the attacks of the borer.

Apples from Sprouts.—I. G. Wolfe, Union Co., Pa. "Like produces like," even in apple trees. Trees from sprouts nearly always throw up suckers or shoots about the trunk. True, they can be frequently cut away; but the tendency to form suckers weakens the parent, besides involving the labor of removal.

Hamburg International Exhibition.

—The following gentlemen have been appointed Delegates: Hon. Ezra Cornell, Ex-President N. Y. State Agr. Soc.; Hon. Dan. Needham of Quincy, Vermont; Ex-Gov. Dyer, of Providence, R. I., and Chas. L. Flint, Sec. Mass. Board of Agriculture.—Messrs. Austin, Baldwin & Co. inform us that several Express Companies agree to reduce their freight 25 per cent. on all articles intended for the Exhibition, viz. American, Adams, National, California, and the Eastern.

Butter and Cheese in Vermont.

In a recent conversation with Mr. G. Merrill, Superintendent of the Vermont Central and Sullivan Railroads, he informed us, that during the year 1862, there were shipped at the St. Albans' Station alone **2400 tons** of Butter and Cheese. This is equivalent to 4,800,000, or nearly **five millions pounds**. Can anyone give us anywhere near accurate statistics of the amount of each, butter and cheese, produced in the whole state? We have one fact of interest, viz., that in proportion to the inhabitants, there are more copies of the *American Agriculturist* taken and read in Vermont than in any other state, with perhaps the exception of Pennsylvania and the "State" of Long Island. Connecticut, Rhode Island and New-York, are nearly on a par with Pennsylvania. On Long Island every Post Office has its club of subscribers to this journal, and many of these clubs are very large. In our own town there are over 200 subscribers, who get the paper through the Post Office and in the city, though no canvass has been made for Premiums, and no other special efforts have been put forth. Not being a "prophet," this of course does not invalidate the general rule concerning that profession.

Willow Hedges.

—James D. Blacker, of Long Island, writes that he made a trial of the Osier willow for a hedge, and found that the roots so monopolized the soil that nothing would grow near it. Potatoes planted near the hedge could only be dug by cutting among the roots of the willow with a sharp spade. A fence of the willow which had been set out four years, sent out roots 30 feet long into his garden.

White Willow.—W. S. Grow, Vt. We have not seen the willow cuttings advertised by any one at the East. The tree is common enough in all old settlements, and doubtless grows in your own State.

Osage Orange Seed.—W. E. Thomas, DeKalb Co., Ill. The seeds should be sprouted by covering with scalding water. When cool, this is poured off, and the seeds kept covered in a warm place until they sprout, when they are to be sowed. If large quantities are sprouted at a time, take care that they do not heat.

Sorghum Seed.—B. Borden, Pa., suggests that pure seed could be obtained by cultivating upon an island or upon a peninsula sufficiently remote from any place where any other variety is cultivated. He thinks if some one would cultivate thus for the seed, he would do a profitable business, and be a public benefactor. [If he gets pure seed to start with.—Ed.]

Lima Beans.—M. Witherill, Saratoga Co., N. Y. "Learns by observation" that Lima beans when they germinate do not come above ground like other beans. This is contrary to our observation. Perhaps his were planted so deeply that the leaves did not reach the surface, but their usual way is to behave like other beans.

To Save Cucumber Seeds.—W. W. Cook, of Hopdale, Mass., says "when the fruit is quite ripe, cut it open and scrape out the seeds into a suitable vessel, add an equal bulk of water and stir well together. In from 24 to 48 hours the mass will become quite sour, when, by rubbing and washing, the seeds may be made very clean. This method will answer for tomatoes or other similar seeds."

Sweet Potatoes kept in Cut Straw.

—We received, March 1st, from Mr. J. C. Thompson of Staten Island, a basket of Nansemond sweet potatoes which were as fresh and nice as the day they were dug. Mr. Thompson practices what he preaches, and the directions he gave for keeping sweet potatoes on page 335 of last volume (Nov. No.) prove eminently successful. It is now satisfactorily demonstrated that sweet potatoes can be profitably raised at the north, and successfully kept until Spring. We gave very full directions for the culture in the last volume of the *Agriculturist*.

Notes on New Seeds.—W. W. Johnson, Penobscot Co., Me., writes that Mammoth Millet distributed from this Office, and sowed by him in May, did not go to seed. In this latitude it ripens seed annually. Spelt, from our distribution, except one head, acted like winter

grain. A package from the Patent Office marked "Bald Barley," contained several kinds of that grain, and numerous *foul seeds*! After sorting, three-fifths proved to be a Bald variety, two rowed, and apparently good. The remainder was the common two and six rowed sorts. "St. James Carrot" from same source, yielded well, was shorter and more tapering than the Orange, was easily pulled without digging, and better than the Orange for the table.

Soot in the Garden.—C. A. Winthrop, Otsego Co., N. Y. Soot, from the amount of ammonia it contains, would be too stimulating for strawberry plants. It is a valuable fertilizer for all root crops. 6 or 8 quarts in a barrel of water will make an excellent liquid manure.

Weight of Turnips.—G. Lee, Middlesex Co., Mass. The laws of different States fix the weights of turnips at 55 lbs. to 60 lbs. per bushel. In Connecticut, where farmers raise many for stock, the weight is 60 lbs.

Black Spanish Winter Radish.

—Geo. E. Lane, of N. H., says that he received some seeds of this and the Brazilian Swiss Chard from the Patent Office, and does not know what to do with the crop.—The radish is eaten by some; the Germans prize it highly. To our taste it is very strong, tough and unpleasant. The Chard should have been used for greens. See article on page 84 of last month. The roots if put out will give you seed next season.

Treatment of the Orchard.

—W. S. Carpenter, of Westchester Co., N. Y., one of our most successful fruit growers, scrapes the trunks of his trees after a day or two of wet weather, and then applies soft soap with a brush. This kills the insects and moss. If the soap, as it is found in the market, is too firm to put on with a brush, it is brought to a right consistence by working it over like mortar.

Pear Stocks.

—"G. N. H.," Jamesport, L. I. Pear stock are more difficult to raise than apple stocks, as they are liable to blight. Very early planting in a thoroughly prepared soil so as to secure an early growth, is recommended. The soil should be manured the Fall previous with vegetable mold, stable manure and ashes, and lime, if the soil does not contain it. Sow in rows three feet apart, or far enough to work with a cultivator.

The Nectarine.

—J. T. McLain, of Morrow Co., Ohio. The Nectarine is quite hardy and will flourish wherever the peach will grow. Where the curculio is abundant, the fruit, like the plum, is liable to be injured. The tree, like the peach, should be pruned in February or early Spring. Cut away half the previous year's growth.

Cherries for Iowa.

—Isaac H. Page, of Wapella Co., Iowa. Dr. Kirtland's cherries are said to belong to the Bigarreau class. If these cherries do well in your latitude, it would doubtless be safe to plant Dr. Kirtland's Seedlings. The Patent Office Report can probably be obtained by writing to the member of Congress for your district.

The Persimmon.

—George Smith, of Hancock Co., Ill. The persimmon prefers a rich and rather moist soil. It is a small tree, sometimes 20 or 30 feet high. It grows wild in some parts of your State. Mr. Thomas Hogg, now in Japan, writes that the most delicious fruit of that country is a kind of Persimmon. He hopes to be able to introduce it here.

Rabbits in the Orchard and Nursery.

—"J. R. D.," Warren Co., Ill., says that rabbits may be kept from young trees by greasing the trunk for about two feet from the ground. He uses either fresh lard or the fat of a rabbit.

Grape Cuttings.

—Isaac H. Page, Wapella Co., Iowa. The Delaware grape is more difficult to raise from cuttings in the open air, than most native varieties. A propagator of our acquaintance succeeds by keeping them moist.

Nursery Catalogues and Tree Planting.

—We have received a large number of Nursery Catalogues, more than we have room to speak of in detail. The one issued by S. Hoyt & Sons, of New Canaan, Conn., deserves more than a passing notice on account of its full directions for selecting, planting, and the after-care of fruit trees. They say: "Never buy or set a tree until you have made up your mind to give it proper care. Order from responsible nurserymen. In planting, expose the roots to sun and air as little as possible. Cultivate the orchard for five years, but do not plow too deep or too close to the trees. Buckwheat is admissible for a crop, but never sow oats or rye. Wash the trunks each Spring with a solution of 1 lb. potash to 6 or 8 quarts water. Ex-

amine Spring and Fall for borers. Cut back half of each season's growth of dwarf trees, for three or four years."

Creveling Grape.

—Mrs. A. R. Sprout, Lycoming Co., Pa., writes that in her locality this is not considered an untidy variety. She says: "We have now fruited many of the new varieties of grapes and are not so easily pleased with new grapes, after having so long enjoyed the superior flavor of the Creveling. The vine, most seasons, requires winter protection."

Bleeding Grape Vines.

—Craig Gilmore, McLane Co., Ill., writes that having failed to stop the bleeding of a grape vine with grafting wax, or a hot iron, he applied a mixture of flour and salt in equal proportions. This had the desired effect. He had seen this recommended in the *Agriculturist* to stop bleeding from flesh wounds, and found it good for lacerated vines.

Keeping Grapes.

—Mr. George Barclay, of Dutchess Co., N. Y., while travelling in France, often saw the grape in an admirable state of preservation, quite out of season. He found the secret of their success in thus preserving them, consisted in coating the clusters with lime. The bunches are picked just before they are thoroughly ripe, and dipped in lime water of the consistence of thin cream. They are then hung on wires, and when dry are dipped the second time, and then hung up to remain. The lime coating keeps out air and checks any tendency to decay. When wanted for the table, dip the clusters in warm water to remove the lime.

Inarching the Grape Vine.

—J. P. Streep, Milwaukee Co., Wis. We doubt the success of this method. Practised in early Spring they will bleed too much for a union, and though they might unite if grafted in Summer, it is preferable to root-graft in the manner illustrated on another page.

Grafting Wax.

—C. Olney says, mix by weight 4 parts resin, 2 parts beeswax, and 1 part tallow, by melting in an iron kettle. Pour it in cold water and work with the hands until it is of an even color.

Shrub for a Name.

—Capt. Ely Sperry, 19th Conn. Volunteers, Fort Worth, Va.—The leaves of the shrub sent to us, appear to be *Euonymus Japonica*, a most beautiful species, but one which will not stand our northern winters. We are gratified to know from the many letters we receive from the army that those who have taken up the sword have not forgotten about the plow, and the garden, and that they remember us.

Seeds for a Name.

—Elizabeth Wilson, Decatur Co., Ind. The "Forbidden Fruit" is called with us Jerusalem cherry. It is very closely related to the pepper, and has the botanical name of *Solanum Pseudocapsicum*. The other we can not recognize from the seed. It will be necessary to send the flower at the proper season. The seeds sent by S. A. Myers, Henry Co., Ohio, look as if they were a species of *Solanum*, but we can not tell from the seeds only.

Milkweed.

—H. E. Rhouls, Montgomery Co., Ind. We do know the milkweed, and have several species very abundant here, as they are everywhere. We know of no use to which the silky fibre attached to the seeds, has been put. We learn from a Belgian horticultural journal that some experiments are to be made there upon its culture, with a view to the use of the fibre of the bark as a substitute for cotton.

A Fine Bouquet.

—J. J. Otto, of Rochester, N. Y., has sent us a bouquet of choice flowers, which came in fine order and graced our Exhibition tables for several days. By means of a frame made of four wire rings of different sizes, and placed one within another, the flowers were arranged so as to present a perfectly flat surface. The wire frame was entirely concealed by the beautiful *Lycopodium* which furnished the green of the bouquet.

Plant for a Name.

—S. S. White, Mercer Co., Ill. The beautifully dried specimen you sent is *Callirhoe pedata*. It has not been long enough in cultivation to have a popular name. We used to see it growing wild in great profusion in Texas, and since it has been introduced to the gardens, it has been among our favorite plants. Sown early, it will bloom as an annual, and with care the roots may be kept over Winter.

Tuberoses.

—"Mac," Sullivan Co., N. Y. After the balls have dried, it is customary to trim off the roots before packing them away. We are glad that you have begun to give animals proper treatment while young.

Exhibitions in Prospect.

Elsewhere we announce a Strawberry Exhibition. The display at the *Agriculturist* Office last year, was the finest one of the kind ever held in this country. So others tell us; the writer was absent in Europe at the time. With the experience of last year as a guide and the many requests for a repetition, we expect to have a still greater affair next June.—A Show of Pumpkins, Squashes and Gourds, is being planned for in Autumn. Other exhibitions of Vegetables, Fruits, Flowers, Sorghum, etc. are in contemplation, but the number, and their extent can not yet be decided upon. The increased cost of paper and other publishing items, lead us to hesitate in the matter. The prizes are a considerable item for individual enterprise, while these are but a small part of the expenses attending upon getting up and carrying through an exhibition. Still, as these displays of farm and garden products tend to excite general interest and improvement, we shall do all we can afford to this year, and more we hope, hereafter.

Good Grape Vine Premiums.

These seem to have met a general want, judging from the tone of the many letters received. We have been able to procure a small addition of excellent vines to our own stock, so that the offer will remain open through April and probably into May. It will be noticed that a slight change in terms is made, viz. one vine for every subscriber in a club of ten instead of fifteen as announced last month. We do this in response to many requests from those who say they can get a club of ten if a vine be given for each, while they can not, at this late day, get fifteen. The unusual cold weather delayed the beginning of the distribution of vines to southern points until March 27th. They will be sent to other parts of the country as fast as the season will admit. See page 128.

This is certainly a cheap and convenient way of obtaining a good vine as a beginning. Where several go to one place those receiving them can, by choosing part of both kinds, exchange cuttings or layers hereafter.

A Special Request to Advertisers.

Every day almost, we receive advertisements from distant parties who are wholly unknown to us personally or by reputation. We must insist upon having references from such persons, or some kind of evidence that they are reliable men, who will do what they propose to do in their business cards, or we can not insert their advertisements at any price. The fact that an advertiser has been a subscriber for several years, does not necessarily make us acquainted with his mode of doing business, though he may know all about ours. The above may seem a hard rule, but it is necessary, for we desire to insert nothing either in our reading or business columns which will lead our readers into an unprofitable investment. It is not enough that a man pays us for space occupied. If for example he advertises trees and plants very low, we want to know first whether he will certainly send them of the *quality* and at the *price* he offers, and what is still more important, will they be *true to name*. The very worst cheating, is to sell trees and plants, which after the expense of getting and years of care turn out to be untrue. The same of seeds, etc.

We are obliged to return many advertisements sent in with the money, simply because we do not know the parties offering them. The above request is not only for the protection of our readers, but also to give value to the business cards of good reliable men. If any object to the requirements, we shall very cheerfully do without the favor of their advertisements.

A Good Time to Buy.

The reader will find a large amount of interesting information on the closing pages of this paper. We have this month allowed business men to have more than their usual space. The advertisements taken as a whole are of an excellent class; a large number from unknown persons, and from known unreliable parties have been refused. While almost everything else has advanced, it will be seen that trees, plants, many seeds and some agricultural implements are offered more abundantly and cheaper than ever before. This is a good time to lay in a supply. It will pay to look through the whole of the advertisements, and see what is for sale, by whom and at what prices. It will cost but little to send for the Circulars and catalogues offered, and thus get acquainted with the dealers. We ask as a favor, that those writing to advertisers will mention that they saw their advertisements in this Journal. We like to have them know who are the wide awake, enterprising readers of the *Agriculturist*, and it will please them also to learn where their business cards are seen by the largest class of readers. See above.

Seed Distribution—Special Notice.

The distribution of seeds must soon close, for want of material. Never before has there been such a call for them, though we announced at first that, owing to several circumstances, the amount provided was unusually small. Just as we closed up the last paper, the envelopes commenced pouring in by thousands with every mail. Two men have done little else, from morning to night for a month, but simply open letters. We have been forced to reduce the seed measures, and send the smallest possible amount to each, or disappoint thousands of others. Every parcel, however, contained enough seed of the annuals to yield a fair supply of seed for another year. As long as we have any seeds left, they will be cheerfully supplied. Any one sending for them hereafter should mark a dozen numbers, and we will select the first numbers down the list, of which we have seed remaining. Of the *Mammoth Millet Seed*, owing to accident, we failed to get as many pounds as we hoped to get bushels, and so, instead of half-ounce parcels, we were compelled to send only a few seeds, as almost everybody seemed to want it. Every seed grown will produce thousands. In several instances the envelopes come with the slip of numbers omitted, or with defective address. This will account for some parcels not reaching the persons sending for them. The mail may have been at fault in other instances.

Reports on the State of the Crops.

It is of the highest importance to farmers and others, that there should be reliable information as to the *condition and prospects of the Growing Crops*, as the harvest season approaches, and soon after harvest, of the yield throughout the country, so that the producers may have some basis for estimating the probable prices. Impressed with this fact, we last season went to a good deal of expense and trouble to collect and publish reliable returns, monthly. It is not too much to say that the reports thus given in the *American Agriculturist* were the best, and most complete yet attempted in this country. But the labor and expenses are so great that it ought not to be left to individual enterprise, though we should continue the work if necessary. Our new Agricultural Bureau at Washington should undertake the work on an extensive scale. We have had some correspondence on the subject, and recently visited Washington to press the matter upon the attention of the Agricultural Bureau, but we found the Commissioner and his associates too busy at the closing of the session of Congress to discuss the details at length. We are happy to be able to announce however, that the matter will be taken hold of. In answer to our request for an official announcement, to be published, we have the following:

DEPARTMENT OF AGRICULTURE.
WASHINGTON, D. C., March 16, 1863.

To the Editor of the *American Agriculturist*.

DEAR SIR:—In reply to yours of the 14th, I am directed to say that the Commissioner of Agriculture is now prepared to carry out the intended plan of collecting such Agricultural Statistics, for *monthly* publication, as shall show the actual and prospective condition of the various crops of the country during the coming season.

Very respectfully yours, JAMES S. GRINNELL,
Chief of Statistical Bureau.

Premium List Still Open.—Changes.

For want of room we omit the list of general premiums. (They are given on page 88 of March *Agriculturist*.) The good articles there offered are worth working for, and can still be secured by forming new clubs of subscribers, or by the completion of clubs partly made up. Owing to the advance in cost, the terms will be changed after April 1st, for the following articles:

No. 1.—*Books*. Same terms as heretofore, in accordance with the prices of books as given on page 127, a few of which are advanced in price.

No. 5.—*Willcox & Gibbs' Sewing Machine*—advanced to \$40 (always including Hemmer and Feller.) Terms of Premium: 79 subscribers at \$1 each, or 112 at 80 cents. This machine is coming more and more into favor.

No. 6.—*Aneroid Barometers* advanced to \$8.50. Terms of Premium: 25 Subscribers at \$1, or 57 at 80 cents.

No. 7.—*The Aquarius*. The New Premium Terms will be: 25 subscribers at \$1 each, or 54 at 80 cents.

Nos. 13 to 18.—*Back Volumes*. The unbound numbers are indexed to these Premiums.

Melodeons.—No. 8, 5 octave: new price \$80 (133 names at \$1, or 252 at 80 cents).—No. 9, 4½ octave: new price \$65 (112 names at \$1, or 197 at 80 cents).—No. 10, 4 octave: new price \$55 (110 names at \$1, or 163 names at 80 cents).—All other premiums will remain the same as last month, at least until May 1st.

The Prize Tobacco Book.

We have just coming from the press, a very complete, practical work on the Culture of Tobacco. It has been delayed a little by two circumstances: *First*, the Committee had *eighty-five* Essays to look over, instead of the expected fifteen or twenty. *Second*, we concluded to make it 48 pages, instead of 32 as at first intended. The price will not be increased, however, but it will be sent, post-paid, for 25 cents. The work contains 48 large pages of plain, practical directions given by thirteen experienced cultivators, residing in different parts of the country. They tell, in a plain, straight-forward way, what is to be done, from the selection of the seed to the curing of the crop. All the details are given. What is omitted by one is supplied by another—some being more explicit on certain points than others.

A Few of the Humbugs.

In previous volumes we have shown up so many of the various humbugs, that our older readers scarcely need any further caution. But a few hints will perhaps be useful to the thirty or forty thousand newer subscribers, who did not see the former exposures. In the February *Agriculturist*, page 36, we took occasion to forewarn the reader against sundry wonderful discoveries in the seed and plant line that would come out in advertisement and circulars as the planting season approached. The March number had just gone to press, when we began to receive from the distant West (not from near home) copies of circulars sent out from Utica, N. Y., offering a new 'Oriental Sugar Plant,' with a very specious statement of its wonderful properties.—Sugar beet seed can be had at any agricultural store for a tenth part of the price asked for it by this Utica advertiser.

A good many advertise for agents at \$50, \$60, and \$75 a month, and "all expenses paid." When replied to, they forward plausible circulars advising you to send them certain sums of money for sample Sewing Machines, or other articles, on which they offer great profits if you undertake the sale of them. If you ever get any return for the money, which is seldom the case, you are told that if you sell a certain amount you can make \$60, \$70, or more.

Certain parties in this city and elsewhere send out one, two, or three copies of a professedly agricultural journal, and offer great inducements to postmasters and others to get up clubs. They get many to send in money, and sometimes pay the premiums, such as they are, but the paper soon stops, and the duped subscribers can get nothing more for their money, and no amount of writing will draw out a word of reply from the nominal publishers. They write to a friend in the city to call and inquire about it, but the reputed publisher is always out of town, or sick—at least he can never be found.

The old lottery scheme is still in vogue. The latest operation is by a party nominally in this city, and not in a back-woods one-house town in New-Hampshire or Vermont, the locality of those we exposed a year or two since. Early in February, Mr. Wm. R. Shipman, of South Woodstock, Vt., received a letter containing a grand announcement of prizes to be drawn in the "Western Art Union Association, Music Hall, London, Indiana," under the management of "Harris & Co.," the drawing to take place February 20, 1863. There was enclosed a ticket numbered 1689. Mr. Shipman, being a sensible man, threw the whole into the fire, and thought no more of it until he received the following letter from New-York, covering a "list of numbers drawing prizes."

"No. 12 Merchants' Exchange, Feb. 20, 1863.

Wm. R. Shipman,

Dear Sir:—You will see by the list that No. 1689 drew a prize of One Hundred Dollars. Now, I wish you to obtain it, and for this reason; should you obtain the prize, and let it be known, and also inform people whom to apply to for tickets, I should be able to sell many more in your vicinity at the next drawing. If you will aid me in this way, I will assist you to obtain the prize, and thus benefit us both. To have your ticket good you must hold the Managers' Certificate. To procure this, send me a letter, dated on the day of the drawing, and enclose Five Dollars, the price of the ticket. As soon as received, I will go to the Managers' Office, and open the letter in their presence, saying, "This letter was mislaid in the P. O., but the money and date is all right." They, not knowing that your ticket drew a prize, will take the money and send certificate. Send immediately, and do not show this to any one.

Truly Yours, C. E. HOWARD."

Hundreds, perhaps thousands of others were each notified that No. 1689 had drawn a prize for them. Several copies have been forwarded to us. Yet many unsuspecting believers in lotteries have doubtless sent in their \$5 each, never to hear from it again. "C. E. Howard," offered to lie for them, and will be equally ready to lie to them. Mr. Shipman and others have betrayed the confidence of the ingenious Howard by sending his letters to us. Wonder what he will do about it.

A Home-made Field Roller.

The above engraving represents a cheap and efficient field roller, of which a sketch and description were furnished for the *Agriculturist* by R. S. Cramer, Mercer Co., Ill. To make it, saw off two sections from a log 20 to 30 inches in diameter—the larger the better—two or three inches longer than wanted when the rollers are finished. Have ready four gudgeons, two of them 12 inches long, the other two 10 inches long, all made of one inch square iron. Round one end of two of them four inches, and one end of the others two inches. Bevel the square ends a little, so that they will drive readily, but do not draw them tapering. Find the centers on the end of the logs and bore in with an inch auger if the wood is hard, if soft $\frac{7}{8}$ inch, to receive the gudgeons. Drive one long gudgeon, and one short one into each roller, leaving the rounded part to project. Take a thin strip of board, bore an inch hole in one end, and bore a gimlet hole as many inches from the center of that hole as is contained in half the diameter of the roller. Put the board on the gudgeon, insert a scratch-awl in the gimlet hole, and scribe the circumference of the roller. With an ax and draw-shave, chamfer the ends down to the scribe; then stand behind the log, and with an ax hew the middle down, using a straight edge to show when it is level with the ends.—Finish off with draw-shave and jack-plane. To get the ends of the roller square, take the two pieces of scantling that are intended for the end pieces of the frame, bore them where the gudgeons are to work, slip them on the gudgeons and prop them up so that the roller will revolve on the gudgeons freely. While another turns the roller, hold a scratch-awl to mark where the roller is to be sawed off. Cut it with a cross-cut saw, turning the roller occasionally, so as to follow the scribe. Leave a projection of half an inch around the long gudgeon, to keep the outer surface of the end of the roller from rubbing against the frame.

To make the frame, use $3\frac{1}{2}$ or 4 inch square scantling, of hard wood. Make inch-and-a-half mortises in the short pieces, tenons on the long ones to fit, and fasten with draw-bore pins, (keys work out). The tongue answers for the middle cross piece. It should be four inches square where the gudgeons enter—dress away a little on both sides of the hole (for the gudgeons) to prevent friction with the roller. The tongue must be hinged to the back piece of the frame in such a manner that the top of the

tongue will be nearly as low as the bottom of the piece to which it is hinged. To make the hinges, take a heavy piece of strap iron, bend the end of it around a $\frac{1}{4}$ bolt-rod, the ends of which shall project an inch beyond the strap, and weld it. Bolt this to the tongue and secure it to the back piece with eye bolts that fit on the projecting ends of the bolt-rod. The tongue is then laid on top of the front piece of the frame, it being notched down two inches, and a long staple made of half-inch iron goes over the tongue through the piece the tongue lies on. This staple is not to hold the tongue to the frame, but should be long enough to allow the tongue to vibrate up and down six inches, but should fit neatly sideways. The object of the vibration is to allow the roller to adapt itself to the irregularities of the surface.

The rollers should be four inches shorter than the width of corn rows, and then it will be just right for rolling two rows of corn at a time. This implement might be introduced with great advantage upon many farms. It is needed for pressing down clods left by the plow, pressing the soil into contact with the seed, leveling mowing ground for the scythe, and compacting light land. It should not be used on moist land, at a time when the ground is so wet as to pack.

A Linch-Pin Extractor.

A model of the implement represented above was forwarded to the *Agriculturist* by Mr. D. C. Voorhees, Somerset Co., N. J., who says it is very convenient for drawing the linch-pin from carts or heavy wagons, particularly when they are held fast by the dried tar or gum from oil used in greasing the axles. It consists of a lever, *l*, about four feet long. A narrow iron rod, *h*, turned to form a hook, is fastened by a pin in an opening about six inches from the end of the lever. To draw a linch-pin, place one end of the lever on the hub of the wheel, let the hook catch under the head of the pin, *p*, raise the other end of the lever, and the linch-pin is readily extracted.

Ergot or Spurred Rye.

Some cases of poisoning which occurred in Brooklyn, N. Y., having been attributed to the use of ergotized or diseased rye as a substitute for coffee, there has naturally been considerable uneasiness among those who are accustomed to use "Rye Coffee." We give the readers of the *Agriculturist* an engraving of the ergot, which will enable them to recognize the dangerous substance and avoid it. On a head of rye will sometimes be seen some blackish spurs, about

half an inch long, in place of the kernels. Only one or two grains in the head may be affected in this way, or it may be the case with every one. Though it bears no resemblance to the grain of rye, it is really one, much changed by the attack of a minute microscopic fungus or mold. This attacks the grain when very young, and causes it to finally present the appearance shown in the engraving, which represents the ergot as it appears on the head, and also two separate grains. The ergot is often nearly an inch long, and having somewhat the shape of a cock's spur, the name *spurred rye* has been given to it. It has a blackish purple color, and although no odor is noticeable in a single grain, when a quantity is together, it has a very unpleasant smell. When the grain is thus diseased, it not only takes on an unnatural shape and appearance, but its chemical character and its properties are also altered; the grain no longer contains starch, but in its place is found a large quantity (over 30 per cent.) of a peculiar oil, and instead of being a nutritious food, it is a powerful poison. In some parts of Europe, where rye is much more extensively used for food than with us, fearful epidemics have been caused by ergot being mixed with the food. Serious convulsions, loss of sight, gangrene, or mortification of the limbs, and death, have resulted from its use. The presence of ergot is not traced to any peculiarity of soil or season; sometimes it is very abundant, and at others the grain is entirely free from it. Nor is it confined to rye, for we have seen several grasses similarly affected, and it is said to have been found in wheat, though we suspect that the latter rarely occurs. From the well known poisonous character of ergot, it will be seen that it is the duty of those who prepare "rye coffee" for sale, to carefully inspect the grain they make use of; those who prepare it in their own families will be in no danger of poisoning, if the ergot, which is so unlike rye, and so easily detected, be carefully picked out.

Seeding Down Lands to Grass.

To best prepare a field for seeding down, attention should first be given to draining. If it is naturally cold and unproductive, or if water lodges in any portions of it, ditches should at once be opened through it, and laid with good underdrains. Surface ditches are apt to get filled, and coarse grasses and weeds grow up in them, which interfere with mowing and prevent the flow of water.—Draining finished, spread the manure and put in the plow. Do both of these works thoroughly. On poor soils manure is important to give the grass a good "catch," and to supply it with food afterward. Deep plowing and a faithful harrowing, are needful to bring the land into fine tilth and to enable the roots of the grass to spread out and penetrate deep where they will flourish in spite of drouth.

It is in dispute whether, in seeding down, a few or many varieties of grass seed should be used. For a pasture, it is obvious that several sorts are preferable to any one. One sort gives us an early growth, but dries up in mid-summer. Another starts later, but holds on well. Others grow best in Autumn; some grow best on light soils, others on heavy; some are fibrous-rooted, and grow best near the surface; others are tap-rooted and draw their food from below. Animals crave a variety of grasses, and thrive best on such a diet. The English make the combination of grasses more of a study than we do. They often sow six or eight kinds of seed, and sometimes more. An experienced farmer of our acquaintance favors only a moderate number, as follows: For seeding an acre, 10 pounds of red clover, 5 pounds white clover, one peck of Timothy, and half a bushel of red-top. He salts this mixture down with two bushels of plaster. Mr. A. B. Dickinson recommends, 6 quarts Timothy, 4 of red-top, 2 of blue-grass, 2 of white Holland clover, and 4 of red clover. When several kinds are sown, that best suited to the particular soil, will generally run the others out, and in time mainly occupy the surface.

Other questions relate to the time of sowing, and whether the grass seed should be sown by itself or with another crop. It is quite a favorite practice to seed down in early Autumn, say September, and usually with rye or winter wheat. The argument for this is, that the preparation of the land for wheat or rye is just what it needs to make the grass catch well and grow well; and that by getting a good start in Autumn, it makes a stronger growth the next season than it would if the seeding were deferred until the Spring. But sometimes, the preceding crop (say potatoes,) is a late one, and can not be got off until October; and sometimes other farm work presses so hard in September that stocking lands to grass can not be attended to. In such cases, spring seeding must be adopted. Get the ground in order as early as possible, and sow with oats, barley, or spring wheat, making the grain crop rather light, so as to give the grass all possible chance. The grain crop will shade the grass plants until they get well started, and then it will be removed in time for the grass to get strong before Winter sets in. If the soil is cold and backward in Spring, it is advisable to plow it late in the preceding Fall: it can then be got ready quickly in Spring for seeding. Some of the best farmers prefer sowing grass seed without any grain crop. One crop at a time, they say, is enough. The grain is a coarser and more exhausting crop, it interferes with the growth of the tender grass, and steals away its food. One of the chief objections to

sowing grass seed alone is, that weeds are apt to get the start of the grass. When grass seed is put in alone, the ground should be cleaned and tilled with special care, and a large amount of seed be sown, so as to occupy the whole surface at once, and produce a fine hay.

For the American Agriculturist.

Notes on Wisconsin Farming.

SOWING SPRING WHEAT IN THE FALL.

Of late years, many of our Wisconsin farmers have observed in the Spring, on Fife wheat stubble, quite a thick growth of self-sowed wheat. In one case, I knew as good a crop produced from a piece of Fife stubble, self-sowed and uncultivated, as was raised on some of the neighboring farms in the usual way. These observations, together with the facts that the wheat crop of 1861 fell much below the average, and that of 1862 was nearly a failure, have led many thinking farmers to make some experiments. I have conversed with many such, and all seem to base them on the same general grounds, viz.: 1st, that the wheat crop of 1860 was quite double the average of previous years, and the seed for that crop was gotten in from two to four weeks earlier than in any other season for ten years before. The inference was, to get the seed in early would increase the crop. 2d, that the Fife wheat will retain its vitality and lay in the ground all Winter, and when the ground is plentifully covered with snow, will make quite a good growth under it. All, too, seemed to have the idea, that it should be sown so late in Autumn that it will not sprout before the ground freezes permanently. Of course it is difficult to determine just when it is going to freeze up and continue frozen. A farmer in Waterford, Racine Co., sowed ten acres, I think, late in November, but it remained open with alternate freezings so long after, that the wheat sprouted before it froze up for good, and the crop was a failure. One of your subscribers in Vernon, Waukesha Co., sowed a field late, and in three days after, the ground froze hard. After the snow went off in the Spring, the field was fairly green with the growing wheat. Before the ground was thawed more than one or two inches, there occurred a beating storm of rain, which washed out and drowned the young plants in places. Counting out those spots where it was destroyed, the piece yielded at the rate of 40 bushels per acre, of a very fine quality of wheat. In several cases, to which I am knowing, this experiment succeeded well last year. Another of your subscribers in Newport, Lake Co., Illinois, sowed September 15, 1861, a bushel of Fife wheat and a bushel of winter wheat on equal quantities of land side by side. The Fife wheat produced 11 bushels of as fine wheat as I ever saw. The bran was much whiter and thinner than spring-sowed of that variety. The winter wheat produced 12 bushels of good quality. Last September he sowed several acres of Fife wheat of spring-sowed, his opinion being, it will produce as good a crop as that seed would, which was the product of that he sowed the previous Fall. But in order to test the matter, he has sowed a bushel of wheat raised from that put in the previous Fall, and a bushel from spring-sowed, on equal quantities of land side by side. I hope after he has thoroughly tested the matter he will give your readers the result. Hundreds of bushels of Fife wheat were sown last Fall at different dates. How it will succeed, is yet a matter of some doubt: I will take pains to inform myself in proper time and let

you know. A large breadth of winter wheat was sown last Fall, I should judge four times as much as was sown the year previous. The reason is, winter wheat for the last two years has done exceedingly well, yielding from 20 to 40 bushels per acre of fine quality; while at the same time spring wheat has done very poorly. In the harvest of 1861 a majority of fields did not yield more than 10 bushels per acre. Bad seasons and the chinch bug will not wholly account for these light crops. Half of it can be laid to quack farming. Here and there I find a thorough, scientific farmer, who never fails of raising a good crop of spring wheat. These farmers invariably take the *Agriculturist*.

Market Fairs.

With all that has been written in favor of these institutions, and the efforts that have been made to establish them, they are still a great desideratum in the farming districts. There can be no doubt that our farmers are losing millions of dollars every year for the want of them. In this respect, the British farmer has one of his chief advantages over us. It is not so much that he has cheaper labor, that his living expenses are less, or that he follows his business more closely, that he prospers, but that he has a steady reliable market near home for every thing that he produces. This gives him a great advantage over us, notwithstanding he has to pay a rent of from ten to twenty dollars an acre for his farm and much heavier taxes than ours. Every farming district in England has its weekly market. If a farmer has fat cattle or milch cows to dispose of, they are driven a few miles to the Market Fair and sold nearly as well as he could sell them in the London market, without the large expense of transportation. If a butcher wants cattle he goes to the fairs to buy. Here, there is a middleman, a drover, between the butcher and the farmer, making his profit, often a very large one, which would otherwise go to the farmer. If the English farmer wants store cattle or seeds, he can find just what he wants at the expense of a morning ride. Here, if a farmer wants a stock of cows he has either to go to a distant market, losing traveling expenses and time, or to take his own conveyance and spend a week perhaps, in picking up what he wants, in his own or the neighboring towns, at such prices as he is obliged to pay. There is no steadiness to the prices in buying or selling, except in the large market towns. The regulation of prices is very much in the hands of middlemen.

But few efforts have been made to establish such fairs in this country, notwithstanding their manifest advantages. It takes time to change from a system in which we have been educated, even though that system be a bad one. There is nothing in our circumstances to forbid the establishment of these fairs and the full realization of their benefits. They began as religious celebrations many centuries ago. We have nothing, except our Annual Agricultural Exhibitions, upon which such market fairs could be grafted, and these are quite too far apart to answer the purpose. The place, however, where such exhibitions are held, generally the city or village in the trade center of a county, would be a good starting point for these fairs. It not unfrequently happens now, that a sale of stock and other products occurs at the close of the annual exhibition. More or less exchange

of products always takes place. Where a Society has grounds and permanent stalls and buildings, all the conveniences are provided that would be needed for the accommodation of market fairs. There would need to be some concert of action to get them started, and generally the men most interested in the County Society are the right ones to project the market fairs and make them successful. They might at first be held quarterly or monthly, and then more frequently as they became better known. Once established they would take care of themselves, as it would be for the personal interest of every farmer in the district to buy and sell in that market. This matter should be discussed at our farmers' clubs, and annual agricultural meetings.

CONNECTICUT.

About Liming Land.

The recent letters received at the office of the *American Agriculturist* have contained more notes and queries on the subject of liming land than on any other topic save that of growing tobacco, which from some cause seems to be just now "all the rage," throughout the country. Without attempting to exhaust the subject of lime, we offer a few hints. The precise action or use of lime is not a settled question. Theoretical agricultural chemists have claimed that, since lime is found in the ashes of most crops, it is one of the essential constituents, and must therefore be found in the soil, or be applied, if not already there, in order to supply the elements of the plants. But this does not explain its action. A single illustration is conclusive on that question. The farm on which we were brought up, though a diluvial or loam soil on the surface, is literally filled with limestones, and rests on limestone rocks which often protrude through the surface. The well and spring water is so saturated with lime as to yield a thick coat of it upon the tea-kettle in a brief time. Yet burned lime, and plaster (sulphate of lime,) have always been favorite fertilizers, because their application has proved to be profitable. Many thousands of bushels of lime have been burned from stones gathered upon the surface, and the burned lime has been applied right among the unburned stones with excellent results. The water flowing from the soil is abundantly saturated with lime in a soluble condition, so that there can be no possible lack of this element for the use of the plants. On this point it may also be added, that in the analysis of many samples of water from wells and springs in all kinds and qualities of soils, and from various sections of the country, we have never yet found a specimen of water that did not contain lime enough to meet the wants of any crop.

With the above and other facts in view, we have come to attribute the chief utility of burned lime to its action as an alkaline reagent to neutralize the acidity or sourness of the soil, and to promote the decomposition of organic or vegetable matters, and fit them to become food for the growing plants.* To a limited de-

gree, also, lime acts as a cement to harden and compact light sandy soils.

The burning of limestone simply drives off its carbonic acid, and reduces it to a fine or powdered condition, so that it is easily mingled with the soil. Simply grinding limestone would not remove its acid and render it caustic; this is only accomplished by great heat.

No rule can be given for judging as to whether any particular soil will be benefitted by lime. Experience has proved that it is often useful both on clays, and on very sandy loams, where there is but a very limited supply of lime naturally in the soil; and that it is equally beneficial on soils half made up of limestone pebbles, shells, and organic petrifications which are composed chiefly of lime. Actual trials are the only sure tests of its utility or non-utility upon any particular soil. With the above theory of its action as an alkaline reagent we may generally conclude:

1. That on new soils, where there is more or less of undecomposed vegetable matter, and some sourness, an application of lime will hasten the preparation of the natural manure or vegetable material, and neutralize the acidity.

2. On cold soils or those which are not naturally thoroughly drained, the water saturating the soil for the whole or the larger part of the year shuts out access of air. The vegetable matters remain in an undecomposed or in a semi-decomposed condition. An application of caustic (fresh-slaked) lime will dissolve and hasten the decomposition of the organic materials, preparing their elements to enter and nourish the plants.

3. This effect will be most marked upon recently drained swamps, and fresh and salt water marshes. Owing to the great amount of vegetable matters, it is often necessary to make a light application at first, or so much of the natural manure will be prepared as to induce too rank a growth of straw or stalks. For potatoes, or for corn which is a gross feeder, there is less danger of an over-dose, than when grass-seed or the grain crops are sown.

4. On dry, sandy soils there is often too little moisture to decompose the organic materials, and an application of lime is frequently useful. As above stated, lime acts mechanically, cements the soil, and causes it to retain moisture.

5. On heavy clay soils, lime is often beneficial for the same reason as in (2) above, though a large application sometimes cements the clay, and is deleterious.

Mode of Using Lime.—The best form of application is, to sow *fresh slaked* lime, in the finest condition possible, and immediately mix it thoroughly with the soil by harrowing and plowing. Some spread it upon the surface, and plow it in. The better way is to first plow the land, then sow the lime and immediately harrow it in well. When spread in heaps and left for days or weeks, it absorbs carbonic acid from the atmosphere, and is then far less active upon the vegetable material within the soil. When fresh slaked with water, it is an almost palpable powder, and can be much more thoroughly scattered and diffused through the soil. If it lay in heaps upon the field, or is air-slaked, it becomes carbonated, and though still friable or in a powdered condition, the particles are a thousand times less minute. Sown as a top-dressing, it acts upon a little of the surface, and some of it is washed into the soil, and we have seen good results from this practice, but the effect is far less than when sown fresh and immediately worked into the soil.

Moistening seed and drying it off with lime, just before sowing or planting, often produces good results. We suppose the little lime thus introduced, sweetens a small portion of the soil, and prepares a little of the organic matter immediately around the seed, fitting it to nourish and give a vigorous start to the young plant. A larger application in the hill, or diffused through the whole soil, would of course prepare more of it for the extending roots.

Lime may be applied at the time of putting in seed, or months before. In the latter case it decomposes the organic matters, but these are mainly retained by the soil in store for the roots of the coming crop. Theory and observation indicate, that the time of application is not material, though we are most likely to diffuse it more thoroughly and evenly through the soil, if it be applied when the seed-bed is being prepared. The additional harrowing then given, aids in mixing it evenly through the soil, which we consider a great point to be aimed at.

Moderate applications, at frequent intervals, seem to be preferable to heavy coatings at long intervals. A cold, heavy, sour soil may receive 30, 50, or even 100 bushels per acre at one time; but on lighter soils 15 to 25 bushels are usually an abundant supply. To apply 50 or more bushels per acre on a light soil, may decompose and use up nearly all the organic matters in the first year, and render it sterile; while 15 bushels may prepare enough organic material to benefit the first crop; and the roots and leaves of that crop will add more organic matter for a succeeding crop. This may explain why lime has after a time been condemned where it was at first in great favor. We know one instance where the soil of a neighborhood was light and sandy. Lime was hauled 30 miles by teams, and very moderately applied—10 to 20 bushels per acre. The opening of a railway reduced the cost to 8 cents per bushel, and one farmer applied 500 bushels to five acres at once, expecting great results. The first crop was a good one, but the field was ruined until a heavy coat of manure was applied, to restore organic matter.

Large applications of lime on a heavy soil, and not thoroughly diffused through it, as when it is spread on the surface and plowed under, often settles in a layer, and forms a compact bed through which the roots will not penetrate freely. We have seen many such instances, and nothing would grow well until a plow was run below to throw it upon the surface, and then the harrow used freely to break up and commingle the hard layer with the rest of the soil.

Oyster-shell lime is by some thought to be preferable to stone lime, because the former contains more phosphoric acid; but it slakes much less finely, and is therefore less intimately mixed with the soil. On this account we should prefer the stone lime, and we believe the general experience is in this direction. Gas lime is similarly objectionable, and until after considerable exposure to the action of air in or upon the soil, it is poisonous to plants. (The use of gas lime is fully described on page 75 of Volume XX, for 1861.)

The above general hints indicate answers to a multitude of questions addressed to us. Any other specific questions we shall be happy to reply to, when practicable. Lime is perhaps the most important fertilizer we have, aside from barn-yard manure. It is useful on a large proportion of all the farms in the country, and may well be tried, where it has not been used. Its effects, the best modes of application, and the *rationale* of its operation, should be carefully observed and studied by cultivators generally.

* One of the facts of chemistry is, that a compound body will be more readily decomposed if there is present another compound or element having a strong affinity for one of the results of the decomposition. Thus: all vegetable matters, in decomposing, produce a considerable amount of carbonic acid, and this has a strong affinity for lime. Hence the presence of lime in a soil hastens the destruction of dead grass roots and other organic materials, and sets the elements at liberty to act as direct or indirect nourishment to the growing crops.

The Potato or Tobacco Worm.

The above engraving represents one of our most voracious and destructive insects. It is shown in its different stages of larva, chrysalis, and imago, or moth. The larva or worm, fig. 1, is a great pest upon potato and tomato vines, and upon tobacco. It is especially injurious to the latter crop, as it perforates the leaves and renders them ragged and worthless. The worm as it comes from the egg is so small as to be unobserved, but having an enormous appetite, it devours rapidly, and soon grows to about twice the size represented in the cut. When not feeding, it lifts up the head and fore part of the body, and remains apparently lifeless. From its resemblance in this position to the Egyptian Sphinx, Linnæus gave the name *Sphinx* to the genus. The larva, fig. 1, is of light green color, with whitish oblique stripes, and has a horn upon the rear end of the body. Though it is repulsive in appearance, it is perfectly harmless to touch, and may be picked off with the hands without fear. After it has reached its full size, it leaves the scene of its ravages and goes into the earth, where it throws off its skin and becomes a brown colored chrysalis, fig. 2. The curious projection, like a handle, is a sheath which holds the tongue of the future moth. The moth or perfect insect, is represented in the engraving, fig. 3, of the natural size. It is of a gray color, with orange colored spots on each side of the body. As there are five of these spots on each side, it is called *Sphinx quinquemaculatus*, or five-spotted sphinx. The moths may be seen towards night flitting about the flowers from which they suck the juices by means of their remarkable tongue, which is five or six inches long. When the tongue is not in use, it is closely coiled up and hidden between the two feelers. From the manner of their flight and feeding they are frequently mistaken for humming birds, and are called "humming bird moths," and "hornblowers." The moths should always be destroyed if possible; by so doing we prevent the production of several hundreds of most destructive worms. Naturalists make one or two other species, which closely resem-

ble the five-spotted moth, and are only distinguished by characters which would not be noticed except by the entomologist. [The illustrations above were in part re-sketched and engraved from figures in Harris' valuable work on Insects, referred to in our March No., p. 71.]

Tobacco Culture.*

PRIZE ESSAY—BY JUDSON POPENOE, MONTGOMERY CO., O.

I COMMENCED the cultivation of tobacco about fifteen years ago; I therefore write from experience, and shall try to give that experience, in a short and plain way.

VARIETIES.—I have cultivated various kinds of tobacco, but have come to the conclusion that what we call the Ohio seed-leaf is the best and most profitable kind for general cultivation. There are other kinds of tobacco that sometimes are profitable, and do well, but most of these do not cure out so well, nor color so evenly, nor are they so fine and salable as the seed-leaf. The Havana tobacco is too small and has not the fine flavor of the imported. The Connecticut seed-leaf I believe to be identical with our Ohio seed-leaf; the difference in the climate may make a slight variation in the quality, but we plant the Connecticut seed-leaf here in Ohio, and I don't think they can be told apart. The most of the tobacco raised in this district is the Seed-leaf, which is strong evidence that it is the best and most profitable to raise here.

SEED.—At topping-time a few of the most thrifty stalks should be left to grow without topping, for seed. When the crop is cut, let the seed-stalks stand, stripping off the leaves and suckers. As soon as the seed-pods are black, the seed is matured; then cut off the seed-heads below the forks of the plant, and hang them in a dry place, out of the reach of mice, to cure. At leisure time, during the Winter, strip the seed-pods from off the stalk, rub them in the hands until the seed is rubbed out, sift through a fine sifter, put in a dry place, secure from vermin of all kinds, and it is ready to sow. I have sowed seed six years

* To our great surprise, over eighty persons sent in essays on Tobacco Culture, in response to our Premium offer. Of these 15 were in German. One of the essays was written by a lady. They were handed over to a competent Committee of three, two of whom were engaged nearly two weeks in examining the manuscripts. They found several very fine essays—some of them excellent specimens of skillful use of the pen; others were rather historical; others were complete and very excellent on some points, but did not contain information on all points. The best one, perhaps, on the culture (by Mr. Schneider), had too little practical information on the important matter of *curing and packing*. The Committee felt constrained to adhere to the terms of the offer, and select the one discussing all points "from securing seed to curing and marketing the crop." Taking all things into consideration, they finally awarded the First Prize of \$15, to Mr. Popenoe, as above. The Second Prize of \$10, to Mr. A. B. Foster, Crawford Co., Wis. The Third Prize of \$5, was so nearly balanced between Messrs. Christian Schneider of Madison Co., Ill., and Oliver T. Bishop and Wm. H. White, of Hartford Co., Conn., that the Committee could not award it to any one of the three; so they decided to recommend the Publisher to increase the amount offered, and pay a Premium of \$5 to each of these gentlemen, which was cheerfully acceded to. All these five essays, and a number of others, are published in book form as noticed on another page.]

old which grew as well as new seed. I think it is a good plan to raise seed enough at any time to sow for ten years, as it is thought to deteriorate by constant raising without changing. If seed snaps or pops when it is thrown on a hot stove, it will grow.

PREPARING SEED BEDS.—There are two plans of preparing beds for sowing seed; the first and best, is to spade or plow a bed in rich, dry ground, with a southern exposure; the south side of a barn is a good place, as the reflection helps to warm the ground. Where you have tobacco stalks, as you make a furrow with the plow or spade fill one third full with the stalks and turn the next furrow over them, and so continue until the bed is broken up. The stalks hold moisture, make the bed warm, and help to drain it. Take well-rotted hog manure and spread over the bed to the depth of about two inches, then harrow or rake until the manure is thoroughly mixed with the surface of the bed, and all is well pulverized and as fine as garden mold. For a bed one rod wide and four rods long, take two common-sized table-spoonfuls (as much as will lie on conveniently) of seed and mix well with four quarts of ashes, or slacked lime, and sow broadcast; the ashes will enable the seed to be sowed evenly; then take a hand-roller and roll the bed evenly, or place a board on one end of the bed, walk on it to press the ground to the seed, move it over, and repeat this until the bed is all pressed over. Another plan is to burn a large brush-heap in a clearing, or on any new ground, in the evening; in the morning dig the ground up with the ashes on; while warm, rake the bed fine and sow the seed as above directed. Very little weeding is required where the ground is burned, as the fire destroys the weed and grass-seeds.

If the weather is dry, the plants will need watering after they are sprouted, (which will be in about three weeks); in fact, the surface of the bed should be kept constantly moist; the beds should be kept clear of weeds; do not let the weeds get a start of your plants, or they will soon choke them out. If the plants grow well and evenly, the above-sized bed will plant four or five acres, but it is always safe to have two or three such beds, to guard against a failure, and to supply your neighbors. The usual time to sow is from the middle of March to the tenth of April, or as soon as the ground admits of working in the Spring. I have known seed sown in the Fall make good plants, but do not recommend it.

SOIL.—A rich, sandy, second bottom, I believe to be the best for raising tobacco, although our chocolate-colored uplands, when very rich and highly manured, will grow an excellent quality of tobacco, but will not yield as much to the acre. Black river-bottoms will yield more to the acre than any other kind of land, but the tobacco is not of so fine a quality; it grows larger, has coarser stems, and heavier body, and consequently, is not so good for wrappers or fine, cut as the second bottom or upland tobacco.

MANURING AND PREPARING FOR PLANTING.—Tobacco is a gross feeder and grows rapidly when once started; it therefore needs plenty of food to make it grow well. There should be a good coat of clover to plow under; if the ground is naturally rich, this alone, will make a good crop; but hog and stable-manure well rotted, is what the tobacco, as well as any other crop, delights in, and the more manure, the better the tobacco. The plan that I am now experimenting on is, as soon as I cut my tobacco in the Fall I give the ground a good harrowing, and then drill in wheat; the ground being well cultivated all the Fall, is clear of weeds and mellow and needs no plowing. In the Spring I sow clover; after the wheat is off, I keep the stock off until about September, to give the clover a chance to harden and spread. I then let the stock eat as low as they want to, which drives the clover to root and causes the crown to spread; I do not suffer stock to run on the clover during Winter or Spring. About the last of May or first of June I plow the clover under, which is now in blossom, and so I alternately keep two fields in tobacco and wheat, at the same time feeding the ground a crop of clover every two years; in this way I expect my land to increase in fertility all the time. The clover turned under, makes food for the cut-worms, and they trouble the tobacco-plants but little. We now harrow thoroughly, following in the same way that we plow, to make the sod lie flat and not drag up; next the roller is put on, and after the ground is well rolled it should be again harrowed, and, if cloddy, rolled again. Make the ground in the best condition possible, so that the roots of the tobacco will have no difficulty in penetrating the soil and searching for food. My plan is to furrow east and west three feet apart, north and south three and a half feet. I plow the tobacco both ways, but do all the hoeing, suckering, etc., north and south. Some mark out the ground 3 feet each way, but I think it is too close. If the tobacco is large, three feet does not give room to work among it conveniently. I mark out the ground with a small one-horse plow, going east and west first, finishing the way that I make my hills. The usual way to make the hills is with the hoe, making the hill where the furrows cross each other, drawing the dirt into a hill about

as large as for covering corn or potatoes. With the flat part or back of the hoc press or flatten the hill down to the level of the surface of the ground, taking care to have it clear of clods or rubbish. I generally make my hills with what we call a jumping shovel—the frame of a single shovel-plow, made light, with a shovel about eight inches square, put on in the place of the common shovel. Hitch a steady horse to this, start him in the furrows, dip the shovel in the middle of the furrows, and raise it, depositing the dirt at the cross of the furrows. Have a hand following to level and put down the hills, and take out clods. In this way I make, with the assistance of a boy fifteen years old, about fifteen thousand hills in a day; with the hoe three or four thousand is a good day's work.

SETTING OUT PLANTS.—From the first to the fifteenth of June is the proper time, although, if it is seasonable, up to the fourth of July will do, but the sooner after the first of June the better. By this time, with proper care and attention, the plants are large enough. The ground should be well saturated with rain, and a cloudy day is much the best. Immediately after a rain, or between showers, call out all the force, for the work is pressing; the success of the crop depends on getting it out at the right time; all hands go to the plant-beds, pull the largest plants, one at a time; don't let two stick together, or the boys will drop them together and a plant will be lost. After the baskets are full, let one hand continue to pull plants. Put the little boys and girls to dropping one plant on the side of each hill; let those who stick, take an extra plant in the hand, drawing the leaves together in the left hand, and with the fore-finger of the right hand make a hole in the center of the hill deep enough to receive the full length of the roots without the tap root bending up; insert the plant up to the collar with the left hand; stick the fore-finger of the right hand one or two inches from the plant, and press the dirt well up against the roots, taking care that the dirt is pressed so as to fill up the hole. Pick up the plant on the side of the hill, and as you step to the next hill arrange it for sticking; in this way you always stick the plant that you pick from one hill in the next, thereby greatly facilitating the work. Sometimes the ground is not sufficiently wet, and the sun coming on the plant is apt to injure it; at such times take a small clod and lay it on the heart of the plant to keep the sun off, removing the clod in the evening. As soon as the plants have started, the first time the ground is wet enough, replant where they have died out.

CULTIVATION.—As soon as the plants have taken root and commenced to grow, begin to use a double shovel-plow, having the shovel next the tobacco, about three inches wide and six or eight inches long; do not go too close to the hill, or you may displace the plant; follow with a hoe, removing all grass and weeds, leaving the tobacco master of the situation. Dig gently the surface of the hill, and draw a little fine dirt around the plant, and strive to keep the soil around the hill as mellow as possible without disturbing the plant. After going over in this manner, plow the opposite way, going twice in a row. Some prefer the cultivator for going over the first two times, and I think perhaps it would be preferable, as it pulverizes the ground better than the shovel-plow. After going over the field twice, in the above manner, commence again with the double shovel-plow, the way the tobacco was planted, following with the hoe, giving it a good hoeing as before. Use your judgment about the amount of tillage needed; keep clear of weeds; keep the ground mellow, and when the plants have spread so that they are bruised by the hoe and plow, stop cultivating.

WORMS.—As soon as worms appear, which is generally when the leaves are as big as a man's hand, go over the tobacco, looking carefully at every plant. The worms usually stay on the under side of the leaf; if you see a hole in the leaf, no matter how small, raise it up and you will generally find a worm under it. Worming can not be done too carefully. Miss one or two worms on a plant, and before you are aware of it the plant is nearly eaten up. When you find a worm, take hold of it with the thumb and fore-finger, giving your thumb that peculiar twist which none but those who are practised in it know how to do, and put the proper amount of pressure on, and my word for it you will render his wormship harmless. Worming must be continued until the tobacco is cut; the last worming to immediately precede cutting and housing.

TOPPING.—The tobacco is ready to top when the button (as the blossom or top of the stalk is called) has put out sufficiently to be taken hold of, without injury to the top leaves. As tobacco is not regular in coming into blossom, it is the usual practice to let those stalks that blossom first, run a little beyond their time of topping, and then top all that is in button as you go. There is no particular light to top at, but, as a general thing, sixteen to eighteen leaves are left; judgment is necessary to determine where to top; if topped too high, two or three of the leaves are so small as not to amount to much; if topped low, the tobacco spreads better. If just coming out in top, reach down among the top leaves, and with

thumb and fore-finger pinch the top or button off below two or three leaves; if well out in top, break off several inches from the button and four or five leaves below it.

SUCKERING.—As soon as the tobacco is topped, the suckers begin to grow; one shoots out from the stalk at the root of each leaf, on the upper side. When the top suckers are from three to four inches long, the suckering should be done. With the right hand take hold of the top sucker, with the left take hold of the next close to the stalk, and break them off, and so proceed, using both hands, stooping over the stalk, taking care not to injure the leaf. Break the suckers about half-way down the stalk, the balance being too short to need removing until the second suckering. In about two weeks from topping, the tobacco is ready to cut; now give it the last worming and suckering, breaking all suckers off down to the ground, and remove every worm, if you don't want your tobacco eaten in the sheds.

CUTTING AND HOUSING.—As a general rule, tobacco should be cut in about two weeks from topping, at which time the leaves assume a spotted appearance and appear to have filled up thicker: double up the leaf and press it together with thumb and finger, and, if ready to cut, the leaf where pressed, will break crisp and short. Do not let your tobacco get over-ripe or it will cure up yellow and spotted; it is better to cut too soon than too late. Take a hatchet or short corn-knife, grasp the stalk with the left hand, bend it well to the left, so as to expose the lower part of the stalk, strike with knife just at the surface of the ground, let the stalk drop over on the ground without doubling the leaves under, and leave it to wilt. The usual practice is to worm and sucker while the dew is on in the morning, and as soon as the dew is off, to commence cutting. There are some who advocate to cut in the afternoon, say three o'clock, let it wilt and lie out until the dew is off next day, and take it in before the sun gets hot enough to burn it. I prefer the first plan, because a heavy dew may fall on the tobacco, and next day be cloudy, leaving the tobacco wet and unpleasant to handle. After cutting allow the tobacco to wilt long enough to make the leaves tough, so that they can be handled without tearing. Great care is now necessary to keep the tobacco from sun-burning; the cutting should be commenced as soon as the dew is off, and all that is cut should be housed by eleven o'clock, unless it is cloudy; from eleven to two o'clock the direct rays of the sun on tobacco, after it is cut, will burn the leaves in twenty minutes; after two, as a general thing, there is no danger of such burning, the sun's rays not striking direct on the tobacco. Have a wagon at hand, with stiff boards twelve feet long laid on the running gears: as soon as the tobacco is wilted so that it can be handled without breaking, commence loading on both sides of the wagon on the front end, lapping the tobacco the same as loading fodder, keeping the butts on both sides—build about two feet high, and so on until loaded.

TOBACCO BARN.—Mine is 50 by 33 feet, with 18 feet posts; the tiers are four and a half feet apart. I hang four full tiers of tobacco, and hang between the purlin plates in the comb, a half-tier; the bents of the frame are 16½ feet apart. I hang on four-foot sticks made of hickory, rived one-half inch by 1½ inches, shaved and tapered at one end to enter an iron socket; I have sawed sugar-tree scantlings 16½ feet long, 3 by 4 inches thick, for the ends of the sticks to rest on and meet in the centre of the rail, 1½ inches resting on it. Some use sawed lath to hang on, but the split and shaved are far preferable. Hanging on fence-rails with twine is going out of use, as it should. I use my barn to store wheat and barley, threshing just before tobacco-hanging. My barn will hang about seven acres of good tobacco.

HOUSING TOBACCO.—The tobacco being brought to the barn, should be unloaded on a platform or bench convenient for handling. An iron socket, about 6 inches long, ¾ by 1½ inches at the big end, tapering to a sharp point, is necessary; the sticks should be shaved so as to fit the socket as near as possible, but do not bring the stick to a sharp point, or it will not lie firmly on the rail. Have a 1½ inch hole bored three inches deep in the barn-post, three feet from the ground or floor; let the hole be bored

HAND OF TOBACCO.

slanting down a little, so that the socket end of the lath may be the highest; put the end of the stick that is not tapered into this hole and the socket on the lath; take hold of a stalk with the right hand, about one foot from the butt end, bring it against the point of the socket, six inches from the butt of the stalk, grasp the butt with the left hand, and give the right hand a firm, quick jerk, to start the stalk to split; then, with both hands, pull it back against the post, and so on until you have the stick full. The stalks should not be crowded on the sticks; four or five inches apart is close enough; eight or nine large stalks are enough for a four-foot stick. Having filled the stick, remove the socket, lay your stick of tobacco on the floor, and go on sticking until the load is all stuck; or it is a good plan to have rails laid on the lower tie, and hang for the present as you stick. While one or two hands are hanging one load, another may be in the field bringing in another. In hanging, have a single block and half-inch rope, with a hook at one end; secure the block near where you hang, place the hook in the centre of the stick of tobacco, and let the man on the floor draw it up to the one who hangs. There should be a stout pine board, two inches thick, fifteen inches wide, and long enough to reach from tie to tie; this should be placed under where you hang, to walk on. When the tobacco is hoisted up, take it off the hook, and walk to the farther end of the board; have your rail placed to receive the stick, and so continue until the rails are full, then move the board and block to another place, and so continue. A sixteen-foot rail will hang about twenty-four laths; eight inches apart is about the distance to place the laths of tobacco on the rails; if too much crowded, the tobacco will house-burn. Care should be used never to let a load of tobacco lie long on the wagon, or in a pile, as it sweats and heats, and is soon ruined. Always keep the tobacco cool. After it is housed, keep the doors open day and night, so that it may have the benefit of the warm and dry air, for the purpose of curing, closing the doors against high winds and beating rains. When cured keep the doors closed.

STRIPPING.—When the tobacco is sufficiently cured to strip, which will be after it has been well frozen and dried out, you will have to watch for it to get "in case" for handling; when a warm, wet, misty spell of weather comes, throw open the doors to allow the tobacco to take the damp. When the stems of the leaves are so limber that they will not snap, and the leaves are pliable, but not too wet, take down a sufficient quantity to strip for two or three days; take it off the sticks, make a temporary crib of boards about four feet wide, and bulk the tobacco in it, laying the tops in, butts out, next the boards. After you have made your bulk, cover with an old carpet, boards, or anything else handy, to keep it from getting too damp, or from drying out. Care should be taken that the bulk does not heat; if the stalks are wet, or there is any uncured tobacco, forty-eight hours is sufficient to spoil the tobacco. During the Winter there are generally several tobacco seasons, and by improving them the stripping can all be done before March. Having the bulk down, we now proceed to strip for market; lay a pile of the tobacco on a bench or platform about two feet high, and let the most careful and handy man take a stalk in his left hand, give it a shake to make the leaves hang out free, then pick off four or five of the bottom or ground leaves, and any badly torn or diseased leaves, and all such as are not considered prime; do not put any frosted or "fat" leaves in, as it spoils the tobacco; pass the stalk that is primed to the stripper, and let him take off the prime leaves. Take off one leaf at a time, keeping them straight in the hand; when a sufficient number are taken off to make what is called a hand of tobacco, take a leaf in the right hand, put the thumb of the left hand on the end of the leaf, about one inch from the butt of the hand or bunch, and pass the leaf around once or twice; an inch is wide enough for the hand; open the hand of tobacco in the centre, pass the end of the leaf through and draw it tight, then squeeze the hand together and lay it down, keeping the leaves straight. An inch and a half in diameter is large enough for a hand. When a sufficient quantity is stripped to commence bulking, make two places to bulk in, one for prime and one for ground leaf; let the space be according to the quantity of tobacco to bulk. A bulk 3½ feet high and 20 feet long, will hold ten boxes, or about four thousand lbs. of prime tobacco; the sides of the bulk must not be inclosed, but left open, so that the butts can dry out; at each end of the bulk put a bulkhead of boards to build against, about three feet wide and four feet high; secure this upright and firm; do not build on the ground, but on a platform or floor. Commence at one end against the bulkhead, take one hand of tobacco at a time, straighten and smooth it, and lay it on the floor at one side of the bulk; take another as above, press it against the first, and so proceed to lay the length of the bulk; then turn and lay down the other side of the bulk, letting the ends of the tobacco lap over the first row about four inches, and so repeat, keeping the butts even. After one or two

rounds are laid, get on the bulk on the knees, and as you lay a hand put your knee on it, and thus pack as close and compact as possible. When not bulking down, have boards laid on the tobacco, and weights put on to keep it level. Keep the ground leaf separate from the prime.

Boxing.—Boxes should be made 30 inches square by 42 inches in length outside; saw the end-boards 28 inches long, nail them to two 1½ inch square slats, so that the head will be 28 inches square; when two heads are made, nail the sides of the box to the heads so as to come even with the outside of the head, the sides being 28 inches wide; then nail the bottom on firmly; the top can be nailed slightly until after the tobacco is packed, when it can be nailed firm. Set your box by the side of the bulk, and let one man get in the box and another pass the tobacco to him, one hand at a time, taking care not to shake it out, but put in the box as it comes from bulk, with the butt of the hand next the end of the box. Place close and press with the knee firmly; lay alternate courses at each end, and if the tobacco is not long enough to lap sufficiently to fill the centre, put a few hands cross-wise in the centre. When the box is full, place it under a lever; have a follower, that is a cover made of inch boards, nailed to two pieces of scantling, and made to fit inside of the box; lay this on the tobacco, and place blocks of scantling on it of a sufficient height for the lever to be clear of the box when pressed. Press down firmly with a strong lever, and, while kneeling in another boxful, let the lever remain so that the tobacco gets set in the box. When ready, take the lever off and fill up as before, about six inches higher than the box, press it below the top of the box, take off your lever and nail on the top as quickly as possible. Some use tobacco-presses for packing, which are perhaps more convenient; they are of various patterns, but a lever saves expense of a press, and is within the reach of all. If tobacco is sold at the shed, it should be sold before packing, being easier examined in bulk than in the box.

Notes on Flax Culture...III.

Before flax can be used by the manufacturer, the fibrous material must be separated from the other portions of the straw. Each stalk consists of three distinct parts, viz.: a woody stem in the center, called the "shoove," or "boon," next to this and surrounding it are the fibers, and outside of all a thin bark or skin. The fine filaments of fiber are cemented together and fastened to the other parts of the stalk by a gummy, resinous matter, which must be extracted in order to separate the filaments and render them sufficiently pliant for spinning. This part of the business is a chemical operation, and properly a separate branch, of importance enough where flax is largely cultivated, to require the services of appliances specially adapted for the work, and skilled operatives to conduct the process. In France a class of men termed "liniers" take the raw flax in the straw from the hands of the cultivator, and attend to all the manipulations necessary to prepare it for the manufacturer. Were this crop grown to a sufficient extent in this country, such a division of labor would undoubtedly soon be made here. In fact, in view of the prospective increase in flax culture, parties are already experimenting and perfecting processes whereby they expect to be enabled to profitably purchase the straw from the farmer and reduce it to the desired state. Until such arrangements are completed, it will be necessary for the flax raiser to follow the method heretofore practised, and to conduct the "retting" as it is termed, upon his own premises. This consists in decomposing the gummy, resinous matter by fermentation and putrefaction; literally rotting it away. It is done by subjecting the flax to the action of moisture and warmth. To this end, it may be steeped in vats, ponds, or sluggish streams, which is called water-retting, or it may be exposed to rain and dew, termed dew-retting. The latter process is almost universally employed in this country. About the last of August, the straw is taken to a smooth meadow, or pasture land,

where it may be kept clean, and spread carefully in swaths, about half an inch thick. Keep the butts even, and make the rows several inches apart, so that the ends of the straw may not become interlocked. If there be not rain and dew enough to wet it frequently and thoroughly, the retting may be hastened by turning it. Many recommend to let it remain until one side is sufficiently retted, before exposing the other. The turning is easily and quickly performed

with a light smooth pole ten or twelve feet long, slightly curved as shown in the engraving. About five weeks is usually sufficient to complete the process of dew-retting. This, however, depends materially upon the state of the weather. Frequent showers and heavy dews may reduce this time considerably. When the flax has turned a silver gray color, and the lint is seen separating from the woody part, particularly at the ends, and when on bending or twisting a small bunch of it in the hands the woody part breaks freely, leaving the lint clear, it is sufficiently retted. When dried it is ready to be operated on with the brake, or to be stored under cover or in thatched stacks, until disposed of.

For the American Agriculturist.

Both Sides of the Dog Question.

The Editor of the *American Agriculturist* indulges in a sweeping invocation to "stir up the public sentiment in favor of enforcing the dog laws." "To shoot or poison every dog larger than a rat terrier, that looks at your premises." Or to "cut their tails off as short as the Dutchman recommended, viz., close behind the ears." "Very good," exclaims the terrier man, "only be careful to discriminate as to size before you shoot, or poison." "Just right," exclaims the little Miss as she pats her diminutive lap-dog. "Capital," says the sheep breeder. "Just right," echo a host of men. And "quite wrong," retort another host. "Partly wrong and partly right," says the writer. We can not do without dogs, and we can not do without sheep. Every one knows why we can not do without sheep. Every one does not know why we can not do without dogs. One reason is, we can not get rid of them. Another is, the farmer can not be secure in his crops, nor sure of his full quota of lambs without them. [We "don't see it."]

But few farmers that have lost from 50 to 100 bushels of corn in one season, as many have, will be in favor of the faithful dog's tail being trimmed as high up as was the Dutchman's dog. Farmers that have urged bounty acts for the destruction of foxes, would much rather see a well known hound's head with a little more tail left on. The truth is, we need well bred and well trained dogs, if any. Our country is cursed with an endless variety of curs that sneak, and stroll, by ones, twos, threes, and half dozens, scattering racket, wool, mutton, and slaughter and confusion, hydrophobia, frightened horses and broken carriages in dangerous profusion. Every owner of a dog should be responsible for his conduct. If he is too poor to pay damages, he is too poor to own any dog, and if he persists in keeping one, let him (the owner) go to jail like a criminal.

We should not tolerate an irresponsible man in our nation. Every owner of a dog should give him every opportunity to chase sheep when he is a puppy, and if he does it, whip him: if he does it again, whip him harder: if he does it again, place the dog at one end of a rope and an old Heenan and Sayers ram at the other end. After a reasonable number of discharges and recoils, loose, and try him again. If he offends again, deliver him over to the *American Agriculturist*, then anticipate the finale.

Mr. Editor, please compromise in your next number, by excepting from your extreme trimming operation all sporting dogs until duly convicted of crime; but if you will not relax from your apparent incorrigibility, do not suspend the writ of *habeas corpus* in case you get my dog in your clutches.

OHIO.

By a curious coincidence, in the same mail with the above plea, came the following list of damages awarded by the Supervisors of Jefferson Co., Ohio, to owners of sheep killed by dogs during the year 1862.

Tristram Frink, Rutland.....	\$25 00

Patrick Boyed, Wilna.....	6 00
	\$287 60

The above was forwarded by Mr. Robert J. Holmes, of Jefferson Co., who fully endorses the crusade against dogs for their sheep-killing propensities and adds: "I find it don't improve a bed of tulips or a collection of choice asters, to have a pack of dogs running over them." If all would agree to have none but well trained animals, and to keep them in place, there could be little complaint; but the laws can not well discriminate, and it is better that a few should lose their favorite dogs than that many should have their flocks destroyed.

"Lampas" in Horses.

The horizontal bars in the roof of the horse's mouth are undoubtedly intended to aid the animal to retain food in the mouth while it is being masticated. They are abundantly furnished with blood vessels and nerves, and are therefore very sensitive. When colts are teething, the disturbance of the adjacent parts sometimes causes these bars to be inflamed and swollen. Then the animal can not eat without pain, and uninformed persons have ascribed the apparent falling off of appetite under such circumstances, to a disease named "Lampas." To remedy the supposed ailment, it has been recommended and is still practised in some localities, to burn out the swollen bars with a red hot iron made for the purpose. The operation is an unnecessary and injurious cruelty. The portion of the mouth thus destroyed, can never be replaced, and thus the power of perfect mastication is impaired. The only surgical operation allowable in cases needing assistance, is to lance the inflamed parts, the same as a physician would treat the gums of

a child in case of difficult teething. This can easily be done with a sharp penknife. After the lancing, it is recommended to wash the mouth with two ounces of tincture of myrrh to a pint of water, or a strong solution of alum in water. Feed the colt on bran mash and grass, withholding all grain until he eats without difficulty.

Care of Harness.

T. Oliver Ayres, a practical harness-maker, Kent Co., Del., contributes to the *American Agriculturist* the following suggestions: "Harness should be kept hung up on wooden pegs in a clean dry room with a plank floor, so that it may be free from dampness. When soiled, it should be washed with Castile soap suds. Harness that is in constant use needs oiling four times a year; if only occasionally brought out, as carriage harness, etc., twice a year will be sufficient, if the washing be not neglected.

To oil harness, separate all the pieces, and lay them in water until thoroughly wet through. Then wash them clean, and allow them to dry sufficiently. To know when they are in good condition for oiling, bend a strap, and if the water does not ooze out, it is dry enough. Train-oil (whale oil) is sometimes used, but neats-foot oil is much better. Mix with it a little lamp-black, and with a brush apply it to both sides of the straps. About six hours after oiling, wash the whole with Castile soap and warm water, let them dry, rub well with a woolen cloth, and buckle them together."

Management of Fowls.

J. E. Hardisty, Harford Co., Md., writes to the *American Agriculturist* as follows: "I keep 7 hens and 1 cock. During the last year, ending Dec. 31st, 1862, each hen laid on an average 128 eggs, and raised two broods of chickens. I feed them well on corn; they were shut up during corn-planting time for four weeks, which shortened the number of eggs at least 130. They lay nearly every day when they can get animal food. If I had any way of providing them with cheap animal food in the Winter, I believe they would each lay 250 eggs a year. My neighbors wonder why they lay so well. My plan for several years has been this: I keep none but the game breed, and but few of them; if a hen does not lay at least ten dozen eggs a year, or if she will sit when we don't want her to, she soon becomes a candidate for the dinner-pot, and never fails being elected, her place being filled by a younger one, to undergo a like ordeal. In Spring I generally have 10 or 11 hens and pullets to select from; by May 1st, 7 or 8 remain; I keep two old favorites that lay well, sit well, and take good care of the chickens when hatched. Cost of feeding each hen 50 cents; average price of eggs 12½ cents per dozen; one quart of corn per day, in the Winter, when they can get nothing else, is as much as ten game chickens will eat."

M. L. B., Greenwood, Maryland, found the profits arising from 3 cocks, 5 hens, and 15 pullets of the Black Spanish, Dominique, and Brama Pootra breeds, as follows:

1584 eggs collected and sold at 16c. per dozen.....	\$21.12
179 chickens raised, at 25c.....	44.75
Total.....	\$65.87
23 dozen eggs set.....	\$3.68
Cost of grain for feed.....	25.51—29.19
Profit on 23 fowls.....	\$36.68

As has been frequently remarked in these columns, poultry raising on a limited scale is far more profitable than when attempted largely.

Many have been induced, by accounts like the above, to enter the business on a wholesale plan. But, even with the best arranged buildings for the purpose, and the most careful management, so far as we know there has been only complete failure. It is not natural for poultry to gather in large flocks. Uncontrollable diseases break out among them such under circumstances, or for some unexplained reason they fail to lay, and become unprofitable. From 15 to 30 fowls properly kept will add largely to the family income, both on the table and in the pocket.

Blinks from a Lantern... XXXIII.

VISITS A BACHELOR FARMER.

Since my reappearance, I have had occasion to reform my notions about the opposite sex. They have grown so much more companionable than they were in my day, that a bachelor of middle age living by himself, is the rarest of birds in the rural districts. I occasionally find one amid a group of maiden sisters, temporarily stalled on his road to matrimony, but so humanized by his surroundings that he is hardly to be distinguished from a married man. This certainly is a very great change in the state of society. Mrs. Grundy, who is quite as much of a woman as she is a farmer, suggests that the sweeter temper of the women of modern times may be owing to the improvement of the men. There may be something in that, for I remember now, that even Socrates was not a saint, according to the modern standard.

I recently, however, heard of a Simon pure bachelor, a real woman hater, who set up for himself forty years ago, and has lived to old age in a house unblest by woman's footsteps. A negro attended to his housekeeping, which was of the most primitive kind, and lent a hand in the field when the indoor work was not pressing. I found Jacob Pennywise the owner of a good farm, by his own earnings. The exterior of the house was not so unpromising, for it had been built for a man with a family. It was a good deal larger than Pennywise needed, but as he could not make it smaller without expense it remained as he purchased it. The barn was a model building, the masterpiece of Jacob's life. He could appreciate the wants of animals much better than those of human beings. By his animals he made his money, and these must be comfortably housed and well fed, whatever else suffered. He seemed to take to animals more than to men, and to have a fellow feeling for them. He always fed them himself, when at home, and this was without exception for forty years. He had never slept under another roof in all those years, and the farthest adventure from home, had been to the nearest market town, seven miles off. He took much more pride in the appearance of his cattle, than in his own. He carded and brushed his working cattle and steers, that he was breaking to the yoke, though, judging from his tangled locks, the comb seldom disturbed his own head. He had noticed

that men who bought oxen were willing to pay something for looks. He used to say it made a difference of ten dollars in the sale of a yoke of cattle, if the hair was kept smooth. He didn't care a straw about looks himself, but if folks wanted looks in cattle, he could make ten dollars as easy by using the card, as in any other way.

He was famous for his colts, in all the county. Nobody raised better, and nobody broke them so well. He had a very handsome income from the sale of animals every year. This was the chief product of his farm, though he occasionally sold poultry, grain, and fruit, when he had a surplus. He was almost as covetous of manure as he was of his money. The cellar was of the full size of the barn, and the droppings of fifty head of cattle all went into this receptacle and were composted with large quantities of muck and loam. He never allowed a rainy day to be wasted. There was always plenty of work in the barn cellar, however hard it rained. There was nothing like manure, he said, to make good colts and steers, and in this he was right.

The management of the barn and of the farm was admirable, indeed I have rarely met with anything more orthodox. But when we come to the management of Jacob Pennywise himself, and of his domicil, the picture changes. I saw at a glance that this was bachelor's hall, where the song of a mother and the merry laugh of children were never heard. There was no carpet upon the floor, no cushioned seat, no rocking chair, no mirror upon the walls, no pictures, not even a lithograph of his favorite horses and oxen. There had once been a coat of white-wash upon the plastering overhead, but it was before Jacob's day. There was a broom in one corner, but it was in the last stages of dissolution, having been used up for tooth picks. There could have been no sweeping done there for many weeks. There was a settee upon one side, and a long table; a half dozen chairs upon another, of the plainest description; a cook-stove and a wood-box upon the third; and on the fourth a long box with a lid, suggestive to more senses than one, of boots and bed-clothes within. This was the sleeping apartment of Scipio, the body servant of Pennywise. Judging from the looks of the lord of the mansion, Scipio's duties were light.

Though Jacob was reputed rich, he was never known to invest in stocks, or to deposit his money in the bank. He occasionally visited that institution, and always carried specie away. He paid his taxes promptly, for he could not help it, but this was his only contribution for the public welfare. His appearance was so seedy that no stranger would think of applying to him for charity, and his neighbors knew him too well to ask aid. He cared nothing for schools or churches, for highways or public improvements. He had about as much as he could attend to, to take care of his farm. He had no near relatives, and was never known to entertain a guest at his house, and he never went a visiting himself.

A few days after my visit I saw the notice of his death. He was found dead on his bed one cold winter morning, by old Scipio. On examining the premises, they found stowed away in various places, gold and silver coin to the amount of over thirty thousand dollars, which was the sum total of all that was left of Jacob Pennywise. Here was a man lost for the want of a woman. He filled no useful place in society. He was a mere machine for making money. The noblest product of the farm is manhood. If the soil can not be made to yield that crop, it were better to lie waste.

Importance of Good Plowing.

The plow will do its work on millions of acres, the present month. The abundant, or meager return in harvest time, very largely depends upon whether that work be well or poorly done. A soil of only moderate richness, if brought to a proper mechanical condition, will feed growing plants far better than stronger land imperfectly tilled. Every one knows that newly cleared forest land usually produces its best crops during the first few years of cultivation. This is not wholly owing to the plant-food yielded by the vegetable deposit which it contains. For many years trees have been sending their fibrous roots throughout its whole substance; scarcely a particle has been left undisturbed. Every square inch is permeated with decayed or decomposed matter. The soil is thus made loose and friable. It holds moisture, admits air and warmth, and the roots of grain or other crops extend unobstructed, and find nourishment at every step. Now, merely manuring such a field will not keep it in this condition. The fertilizing material must be distributed throughout the soil, not only that it may be readily appropriated by the growing plants, but that it may aid in keeping the soil in proper mechanical condition. Those who advocate only top-dressing, lose sight of this fact. The stimulating properties of manure will undoubtedly be felt by the soluble parts being carried to the roots by rain, but an important condition for plant growth will still be lacking. Perhaps for the same reason, in part, guano and other concentrated manures are beneficial for only a limited period. This also explains, in part, the favorable action of clover in rotation: the decaying roots are distributed throughout the soil more evenly than could be

done by any method of manuring now practised. The illustrations are given to enforce the importance of good plowing. The very best execution of this process will only partially supply the most favorable condition for growth. Every care should therefore be taken to have the soil as thoroughly pulverized, and manure as finely mixed through it, as is possible. Good plowing can not be done on clayey land while wet. The furrow slice may roll smoothly as from a brick mold, but it will be compacted into lumps which no harrowing will reduce. A crop put in two weeks later than ordinary on ground in good condition, would stand a better chance than if sown on a field of lumps. The advantages of draining, will be readily seen at plowing time. On drained ground a week or fortnight is often gained for growth of crops.

Much will depend upon the excellence of the implement used. We cannot name the best plow, for the reason that the styles must be varied on the different soils. A variation of one or two inches in depth of plowing may require a radical change in the implement. A plow working easily on stubble may entirely fail on sward. As a general rule it is safest to use a plow adapted for deep work. It may be adjusted to run light; but a plow for shallow work, can not be made to go deep effectively. If possible, purchase a new plow only on trial at first. If it runs with light draft, turns a furrow slice well at from four to eight inches is easily kept at uniform depth, and is well put together, it is a good implement.

A good plowman strikes a straight furrow, leaves it clean behind him, and the surface of the field as nearly level as the nature of the ground will admit. No written instruction will explain how this can be done. A man must learn the art at the plow-handle, and it will re-

quire thought and ingenuity as well as strength and agility. Paying a few dollars extra to an expert hand at this business, rather than entrusting it to an awkward bungler, will in the end be found to be a profitable investment.

Improvements on the Corn Marker.

We have received from Mr. David C. Voorhees, a very neat model of the New-Jersey corn marker described in the *Agriculturist*, page 41, (Feb. No.) fitted with several improvements of his own. These may be readily understood by referring to the engraving previously published, as noted above. The guide pole is attached to the forward beam of the sled where it will be less liable to throw the runners from the track, in marking uneven ground or in meeting any obstruction. A convenient seat is attached, supported by four legs inserted in the beams. A lever or handle three or four feet long is fastened to the rear beam, by which to adjust the sled to its place when starting, and to lift the rear end in turning. The most essential improvement appears to be attaching a cast steel cultivator share or tooth to the back end of each runner, near the bottom. These make the marks more distinct and leave the soil loose. They also prevent the runners from being easily thrown out of place. The cultivator teeth can be procured at small cost at almost any implement store.

How to Stop a Leak—Manure.

A subscriber, "D. C. V.," Blawenburg, N. J., writes as follows: "It is not a cement or patent Gutta Percha liquid for stopping the holes in an old roof, to which I refer, but a way to stop the leaking of golden streams of liquid manure. I call them golden, for who can tell how many

bushels of wheat are running away in this manner? Hints thrown out by the *Agriculturist* about saving manure, led me to look into my own system of making a return to the land for what had been taken off. I thought of the rich stream that was flowing from the barn yard through a ditch that had been dug into a field, for the purpose of drying the yard, which was not only a waste, but was also spoiling a piece of good land along the ditch, where little but weeds would grow. To remedy the evil, I made a pond nearly as long as the width of the yard, twelve feet wide, and eighteen inches deep. With the coarsest dirt I threw up a bank on the lowest side; the remainder was thrown in the pond again. The yard has inclination enough to run the liquid into the pond, and as fast as any liquid makes its appearance there, I throw in any kind of muck, good soil, rubbish, chip dirt, leaves from the woods, etc." Where nothing better can be devised, such an arrangement as this will add many loads of the best manure to the amount that should be used on thousands of farms.

Fig. 1.

Some Observations on the Plum Knot.

BY C. F. AUSTIN.

This disease is not produced, as many suppose, by that great bugbear the curenlio, nor by any insect whatever; neither is it a "cankorous disease produced by vitiated sap," as some imagine, but is simply a *fungus*, which, germinating on the bark of the plum or cherry tree, penetrates to the wood, and increasing rapidly in size, ruptures and displaces the bark, soon forming an irregular naked excrescence, six inches or more long by about one-half inch in width. Its fungoid character was detected more than 40 years ago, by L. D. von Schweinitz, a renowned botanist of Pennsylvania, and described in his "*Synopsis Fungorum Carolinianæ Superioris*," under the name of *Sphaeria morbosa*. Yet it is evident, from his remarks in his "Second Observations on Fungi," (published in *Trans. Philos. Soc.*, Phila.) in 1832, that he had never examined the excrescence further than to find its fungoid character, and seems to have held the idea that it was produced by the joint action of a fungus and an insect. That it is a fungus is evident to any one acquainted with this class of plants. Even the sub-genus to which it belongs may be readily determined without the aid of a lens, and its habit is so different from that of galls, that it is to be presumed no person who is accustomed to watch the operations of insects would pronounce it an insect-gall. It always appears on wood at least one, and seldom on that less than two years old, and always ruptures the bark or cuticle, and exposes itself to the influence of air and light: while, on the other hand, galls always appear on the present

season's growth, and possess a covering formed from the cuticle of the plant upon which they grow, by cell multiplication. Their internal

Fig. 2.

substance is formed directly from those cells existing at the time it was stung by the insect.

In the Plum Knot the case is entirely different; its substance originates (covering and all) from a spore, such as is represented in Fig. 3. One of these spores, under favorable circumstances, when attached to the bark of the plum or cherry, divides itself into two cells, each of these into two or four, and each of these again into two or four others, and so on until very quickly a large tumor is formed, which occupies the place of the bark which it has forced off. How deeply it penetrates the wood, my limited observations do not reveal. I have not found it extending to the pith, but it penetrates the present and, sometimes at least, the former season's growth, splitting it up into bundles that are frequently widely separated from each other by the loose cellular tissue which this parasite, by its own proper growth, has thrust between them, appropriating their sap, and arresting their growth. They make their appearance from May until October, and at a certain stage of their existence become thickly covered on their outer surface with *perithecia*, (spore cases,) which, though small, are quite distinct to the naked eye. Fig. 1 represents a magnified cross-section of a diseased branch. (In this figure the dark lines and shaded portion, except at *B*, represent the fungus; while the white portions represent the proper wood of the branch.) *A*, perithecia, (spore or seed bearing organs): some of them cut longitudinally, showing the cavity in the upper part, which contains the spores. *B*, old bark. *C*, the present year's growth unaffected by the fungus. *D*, *D*, the same affected, the fungus penetrating it and splitting it up into bundles. *E*, previous year's growth, unaffected. *F*, pith, unaffected.

The perithecia (*A*) are of a shiny black color, oblong—club-shaped, or bud-shaped, with the apex at first rounded, then flattened, and afterward depressed: soon a little hole appears in the center, which increases in size until finally they become cup-shaped (fig. 2 and fig. 1, *A*). In the upper part there is a round cavity filled with a white substance composed of *asci* (spore sacs), fig. 3; these are club-shaped and contain several oblong spores as represented in the figure. The *asci* are mixed with a glutinous and filamentous substance. Some of the perithecia have very numerous smaller elliptical spores (fig. 4), which do not appear to be contained in sacs; these are considered by botanists as the *antheridia*, or male spores of the fungus.

Remedy.—This deadly disease, can be more easily eradicated than any other we are acquainted with. Let every person having plum or cherry trees, attend to cutting off and burning the excrescences two or three times each year—

say in June, July and September, always being careful to eradicate every particle of the fungus, for if a solitary uninjured cell of it be left, it will rapidly increase by multiplication exactly as if it were a spore, and will soon break out again. In the mean time let the trunks and larger branches of the trees be thoroughly scrubbed with strong brine, say twice during the season to destroy any spores that may have lodged on the bark, and at the end of three years this pest will have become almost literally exterminated. After that it can easily be kept down with proper care.

I believe it does not exist in Europe, and in this country is confined almost exclusively to cultivated species of the plum and cherry; and as long as the practice so common in this country of depending upon the suckers to keep up a supply of these fruit trees is continued, we may eradicate this disease, but another will surely come in its place, and doubtless one that it will be impossible to get rid of without returning to a more rational method for our stock of trees.

It is a notorious fact that not a single race of cultivated plants in this country is ever permanently injured by any disease either of insects, fungi, or the rot, that has not for a long time been propagated by some method other than the seed, to a greater or less extent. Nature abhors imbeciles and sickly creatures, and has her troops of obedient servants in all parts of the earth which she employs to remove them from her sight. Let us remember that all her purposes are fashioned by the highest Wisdom.

I have never seen this fungus upon our native species of the plum and cherry, except in old fence-rows where they had become sickly through repeated attempts to exterminate them with the bush-hook, and where the suckers would still persist in encumbering the ground, though they had

Fig. 4.

so far degenerated as to be incapable of assuming one-tenth of their normal size. In such places I have seen it on all our species except the Beach-plum, which is probably protected by the salt atmosphere peculiar to its locality.

These excrescences split up the bark of the tree, forming admirable places in which insects may deposit their eggs, and which they are not slow to discover; but out of scores of specimens examined, I have not been able to find either their eggs, or larvæ, except in old and partially effete ones; yet that they themselves are subject to the depredations of insects, I have not the slightest doubt; it would be a wonder were this not the case.

Are Earth Worms Injurious?

A. Beebe, Medina Co., O., writes to the *American Agriculturist* as follows: "In three instances where my garden had been treated freely with stable and barn-yard manure for a series of years, and thoroughly worked—never when too wet—angle worms, in a measure, destroyed its productiveness, and added more than twenty-fold to the labor of working it. In the spring plowing and spading, I have often plowed up and thrown out bunches of angle worms nearly as large as a man's double fist, where there was not as much as a spoonful of dirt among them. I think that all over my garden, the weight of the worms was fully equal to the weight of one-twentieth part of all land stirred by the plow. The land would plow moderately mellow, with some lumps. But three days

of sunshine after a smart shower, would render the ground almost as hard as a well-traveled road. But little impression would be made upon the ground by striking with a hoe as hard as it would bear without breaking. It was necessary to use a pick to get sufficient dirt to earth up potatoes, and after an immense expenditure of labor, they were worthless. This was also the case with cucumbers, squashes, pumpkins, beets, carrots, and parsneps. After two or three years' trial I suspected the cause, and seeded to clover, which produced an enormous crop. The third year after seeding I plowed again, and had good mellow ground to work, and an excellent garden. The land was a mixture of clay and gravel, with good natural drainage, the clay predominating—good land for wheat. I presume there are hundreds of highly manured gardens in Western New-York, rendered unproductive, indurated, and spoiled, by angle worms.

REMARKS.—Unless it can be shown that clover expels worms from land, the above experiment would merely indicate that the naturally heavy soil had been ameliorated and made more friable by the clover roots. The large amount of vegetable matter left in the earth by a good crop of clover, acts very efficiently for this purpose. We can not consider the experiment conclusive as to the hurtfulness of earth worms.—Ed.]

For the American Agriculturist.

Turning Losses to Profit.

Some time since I had occasion to pass by one of my neighbors, and found him employed in skinning his only cow. I expressed my sympathy for him. He good-humoredly replied that with every loss there was some profit; that feed was very scarce, and he was now relieved from all further trouble on that account; and furthermore, he could now pocket the money for the hide, which he could not have done had the cow lived. While musing on the calm and considerate philosophy he manifested under his loss, it occurred to me I had a similar case at home, and whatever consolation there was in my neighbor's system of financial ethics, I had a right to appropriate the benefit to myself. It is, perhaps, more or less true of every rural district in the Western States, that in them are found a few little-souled American farmers, who are not content with the annual income of their own farms, but appropriate the streets, lanes, and all other open lands of the neighborhood, as summer range for their flocks or herds.

But I now come to the point. Several years since I purchased some sheep from a distance, and in this purchase I innocently, but unfortunately, as I then thought, found I had introduced on my farm that bane of the ovine race, the *Foot-rot*. As soon as I ascertained the fact, I gave notice to my neighbors, promising to confine my flocks to my own premises, and frankly and pointedly stating the risk those would incur who would permit their flocks to roam over the country without restraint. To me this miserable disease was a source of anxiety, labor, and loss; but in the improved morals of trespassers, and to the public at large, it proved to be great gain. From thenceforth every man's sheep were kept at home, where they should be, and the neighborhood was thus relieved from this vexatious annoyance. I do not claim any patent right for my discovery in thus converting men into better citizens, neither do I claim much credit for my disinterested benevolence in the case referred to; but my ex-

perience suggests that, because the teachings of the Bible fail in indoctrinating all men in the first principles of practical morality, such cases should not be despaired of as hopeless. And where the conscience can only be reached through the breeches-pocket, every reader must determine for himself when it is expedient and proper to submit to a similar inconvenience and loss, that a greater gain may be secured to the whole community of which he is a member.

Moore's Salt Works, Ohio, February, 1863. G.

[We of course do not recommend the introduction of the foot-rot as a means of improving the morals of a community. We knew of a man who put broken glass into the road ditches and "mud-puddles" along his farm, to keep his neighbor's hogs from wallowing there. His own swine playfully jumped into one of these puddles, and one nearly severed his foot in two upon the sharp edge of a broken junk bottle, rendering him partially crippled for life. Kindness, patient reasoning, and the inculcation of good principles, and neat habits, and a spread of improvement, by introducing books and papers treating of agriculture and horticulture, will be the cheaper and better mode in the long run.—Ed.]

Analyzing Soils and Plants.

W. L. Robbins, of Suffolk Co., N. Y., thinks it would interest other readers of the *Agriculturist* as well as himself, to have published a table showing the chemical constituents of the different kinds of farm produce, so that the cultivator, by having his soil analyzed, could raise in rotation that class of plants best suited to it. There are plenty of tables of this kind, such as they are. Johnston's *Agricultural Chemistry* is full of them. Ten or twelve years ago we printed a large Chart closely packed with these kinds of analyses, but now esteem them of little practical value. By the aid of chemistry we are able to know to within a hundredth part of a grain the composition of soils and their products, yet we can make little use of this knowledge. For illustration, we know that the ashes of wheat contain a large amount of phosphoric acid, and turnips but little, yet an application of phosphates to the soil does very little good to a wheat crop, while the superphosphates are the great turnip manure in England. This subject we discussed at some length in Volume XIX, pages 105-6, (1860).

Start the Tomatoes Early.

Those using hot-beds will have their plants up by this time. Those who have no hot-beds can yet gain some weeks by starting them in pots or boxes in the house. After the plants are up and have made two or three rough leaves, transplant them into small pots, and give them plenty of light and air. The small thumb-pots may be used for the first potting, and as they are so small that they readily dry out, a number of them may be placed in a box and surrounded by moss, saw-dust, sand, or anything that will retain moisture. When it is found by turning out the ball of earth that the roots have filled the pot, they may be shifted to those holding about a pint, taking care all the time that the plants have abundance of air and light, and grow stocky. They may be kept in their pots until all danger of frost is past, when they are to be planted out by turning out the ball of earth from the pot. The directions for after-

culture will be given at the proper season. Earlier and better fruit is obtained upon light and sandy soil than from a wet and heavy one. The small pear-shaped and the smooth red varieties are the earliest. The Fejee is a few days later, but is so much more prolific and finer every way, that were we confined to one sort we should choose this. From a single year's experience with the French Upright, or Tree Tomato, we think well of it. It is a very compact and dwarfish variety, bearing its fruit close to the main stem. It needs but a single stake to keep it from being blown over, and as it can be planted as near as 15 or 18 inches, probably as much fruit can be got off the same space as from any other variety. It must be started very early, as the fruit is a little late, but it is very solid and, according to our experience thus far, every way desirable. Those who have no gardens, but have room in the yard to set a barrel or two, can obtain a supply of Tomatoes with a little trouble. John A. Briggs, of Franklin Co., Mass., writes: "Take a flour-barrel, knock out both heads, saw it in two in the middle, place the halves in any vacant place, fill about two-thirds full of earth, and manure and set your plants in them, and you will find your plants, if attended to, will do as well as in any other place. The writer of this has practised this method for the last three years with perfect success. None need wait for this delicious and healthful fruit unless they are too indolent to try the experiment." The plants grown in this way may be watered with waste water from the kitchen.

For the American Agriculturist.

Sweet Potato Culture.

One page 6, January No., you say sweet potatoes will pay when planted south of 42°. To show that you are correct, I give you the result of a measured plot. From 13 rows, 3 feet apart and 100 feet long, I gathered 43½ bushels of fine potatoes, 36 bushels of merchantable potatoes, and 7½ bushels of small ones to use for seed.

Mode of Culture.—To cultivate with success, select a sandy soil if possible; if not, then the driest location; *don't move the ground* under the hills or ridges formed for setting the plants. If hills are made, deposit a shovelful of manure on the ground, draw the earth up over it forming a hill 10 or 12 inches high, leaving it a little flat on top and it is ready for the plant. If planted in rows, strew manure (half rotten will do) on the ground every three feet, same as for Irish potatoes. Manure don't hurt them; leave the base under the manure about a foot wide undisturbed. With plow, spade, or fork, make the earth fine between the strips of manure, and throw it on the manure into a ridge 10 or 12 inches high.

Rake off the ridges so as to leave them flat and about 3 inches wide on the top: they are then ready for the plants. The ridges may be made ready long before it is time to set the plants. Setting time from May 10th to middle of June, the earlier the better when danger of frost is over.

When the vines begin to run, lift them two or three times, and lay on the top of the ridge. Keep down all weeds; an 8-toothed cast-steel rake is best to dress the sides. Rake the earth from the bottom to top of ridge to cover and smother the weeds. Run the rows north and south if possible. Planted on *hard ground* they grow thick and chubby, but on soft ground they grow long, thin, and comparatively worthless.

Keeping.—After the first frost, dig on a dry clear day, handling with care. After drying a

few hours pack in barrels or boxes alternate layers of short dry or cut straw and potatoes, and move to a warm room or dry warm cellar; if to a cellar, keep up from the floor and off from the wall. With such treatment they will keep eight or nine months.

J. C. THOMPSON.

Staten Island, N. Y.

Early Peas.

In this latitude these may be sown the middle of April, and in some seasons, even by the first of the month. The young plants will endure a pretty severe frost, and may even be covered by a late snow without injury. A warm, dry, rather sandy spot, which last year bore some well-manured crop, should be selected, and if protected on the north by a tight fence or wall, so much the better. Lay off the rows $2\frac{1}{2}$ to 3 feet apart for the taller kinds, and 1 to 2 feet apart for the dwarf sorts. We prefer a somewhat scattered drill for the dwarf, and even for the tall growing sorts. This is made by scooping out the width of a garden hoe, and about two inches deep. Some prefer a single, narrow row, and others plant in double rows 6 or eight inches apart. If the seed is soaked for 24 hours before planting, in tepid water, they will come up much sooner than when sown dry. Cover with a hoe or rake, and after they are up, keep the ground well stirred and free from weeds. The kinds which need support, should be furnished with brush when they are a few inches high, and before they get so tall, as to fall over. A few short rows may be forwarded by a little extra care. Have the rows run east and west, and set up a board upon the north side; this will reflect the sun in the day time, and may be laid over the plants, upon blocks or other supports, at night. In this way the peas will be protected from frost, and the heat the ground has received during the day be retained. Some go to the trouble of making a more complete covering by nailing together two boards, as for a trough, or gutter: this can be put by the side of the plants by day, and at night is turned over them and forms a complete roof. The early varieties are numerous; for the tall growing sorts we have found the Daniel O'Rourke and Princess perfectly satisfactory. The Washington and European are also good early sorts, and recently a variety called the Electric has been introduced, which is claimed to be the earliest kind. We are each year more in favor of the dwarf varieties, as the laborious operation of bushing is dispensed with, and they can be planted much nearer together. Tom Thumb is a good early and remarkably dwarf sort, but as a variety for the family garden, it has the disadvantage that the pods all come to maturity about the same time. Bishop's Long Pod is an excellent sort, as is the Prolific or Strawberry, but neither of these are among the very earliest.

Large Sugar Beets for Stock or Sugar.

The March No. of the *Agriculturist* contains some information on "Beet Sugar," by Prof. Mot, of Ohio. Having made some experiments on beet culture, my experience may be of service to many of your readers. On a plot of ground 38 by 57 feet, planted in June (too late by two months) the product was, by actual weight, 4,226 lbs. They were planted 18 inches by 2 feet—should have been 2 feet each way. This is the secret of success. They want space, light, and air. Manure and prepare the ground

deep and thoroughly the last of March, or as early in April as possible—*frost don't hurt beets*. Drop two good seeds every two feet. Where the plant is large enough, thin out to one, leaving the best plant. I haul the earth around to steady them—cultivate well, and keep clean. I found where self sown seed (dropped from seed beets) came up very early and were left singly to grow where they started on good ground, by digging the ground up around them they would grow to over 30 lbs. each.

My neighbor, Dr. F. Hallick, grows them for stock. In 1861 the seed came up badly and left them thinly scattered: many reached 20 lbs. each. In 1862 he planted 18 inches by 2 feet. This crop averaged 13 lbs. each. This Spring he intends to plant 2 feet each way. Remember to plant early. Deep culture, and good ground are essential to get a fine crop. Do not pull off the under leaves—it stops the growth of the beets, and pock-marks all the remaining leaves.

Staten Island, N. Y.

J. C. THOMPSON.

Early Sowing.

A few bright, warm days, such as always occur the latter part of April, are usually sufficient to bring on an attack of the planting fever. The garden must be plowed or spaded, beds laid off, and in go the beets, carrots, parsnips, turrips, etc. They find a cold bed, the soil is packed over them by repeated rains, and many of the seeds rot outright, or the slender germs fail to lift the heavy soil pressing upon them. It is far better to leave sowing most seeds until the ground is dry and warm. A few of the hardy sorts, such as early peas, potatoes, onions, lettuce, tomatoes, radishes, spinach, salsify etc. may be put in during the month of April, but May 15th is sufficiently early for the generality of seeds. They will then come up quickly and grow rapidly; every one knows, that a quick grown vegetable is far better than one which has taken a whole season to mature. Beets for late fall and winter use do best when sown from the first to the middle of June.

For the American Agriculturist.

The Yellows in Peaches.

BY E. E. CHAPIN, HAMPTON CO., MASS.

The yellows, though easily distinguished by the weak, sickly sprouts with yellow leaves, from which the disease takes its name, seems to be a malady of the nature of which but little is yet known. The most intelligent cultivators who have written upon the subject can give no other remedy than the severe one of destroying the tree, root and branch, as soon as the disease makes its appearance; the remedies of hot water and hot ashes already proposed by some of your correspondents would certainly seem preferable to this, for if they should destroy the tree they would kill the disease with it, and it is quite possible that a cure may be effected in this way without destroying the life of the tree; my reason for thinking so is this: I noticed the yellows had made their appearance upon a young tree that had just ripened its first fruit, about the 1st of September last. I immediately began to examine closely, and found that the twigs presented nothing unusual; there was about a foot of well-ripened wood, with large dark-green leaves, but upon the body and main branches was a large number of sickly yellow sprouts, most of which were already dead at their ends, though they could not have been more than three or four weeks in growing.

The bark of the tree was good, although it had a rather dry, feverish appearance. On digging away the soil at the root there was not the least appearance of any grubs, the bark was perfectly smooth and to all outside appearance healthy, but on applying the knife, to scrape away a little dirt, I was surprised to find that the outer bark would scrape away as easily as a piece of horse-radish, and disclosed much the same appearance underneath. There was, between the outer and inner bark, a coating of whitish substance, very brittle, full of sap, and easily scraped away, and about one-fourth of an inch in thickness at the thickest part, which was about an inch below the surface of the ground, and extending completely around the collar, there being no appearance of it above the surface, and a gradual decrease, as it went down, until there was little or none at the depth of seven or eight inches. After scraping away all of this substance that could be found, leaving the inner bark exposed, I placed fresh soil around it, and then cut away all the yellow sprouts. The tree appeared perfectly well afterwards, and retained its leaves fresh as late as any others. When a tree has such a covering as this one had, I can readily believe that boiling water or live coals, sufficient to destroy the life of a healthy tree, might be applied, not only without injury, but with benefit, if it should slough away the parasitic growth.

What Apples to Plant.

The Fruit Growers' Meeting at the *Agriculturist* office have recently given the above subject special attention. Lists were submitted by experienced cultivators, and votes were taken in the same manner as has previously been done with pears and grapes. The following list by Parsous & Co., for 15 varieties for an orchard of 50 trees, was almost unanimously adopted.

SUMMER.	WINTER.
Yellow Sweet Bough.	Jersey Sweeting.
Yellow Harvest.	Rhode Island Greening.
Primace.	Hubbardston Nonsuch.
Red Astrachan.	Baldwin.
AUTUMN.	Peck's Pleasant.
Gravenstein.	Roxbury Russet.
Porter.	Newtown Pippin.
Fall Pippin.	Talman Sweet.

One or two persons thought the Roxbury Russet and Newtown Pippin did not succeed well enough in all localities to be universally recommended. For those who wish to plant largely, Mr. Carpenter, who has an orchard of 30 acres in Westchester Co., proposed the following 20 varieties, with the numbers for 1000 trees.

SUMMER.	WINTER.
25 Primace.	50 Hubbardston Nonsuch.
15 Sweet Bough.	50 King Tompkins Co.
12 Yellow Harvest.	25 Talman Sweet.
50 Summer Pippin.	25 Dutch Mignonne.
10 Summer Queen.	200 Baldwin.
10 Red Astrachan.	200 R. I. Greening.
FALL.	50 Smith's Cider.
50 Gravenstein.	25 Peck's Pleasant.
3 Jersey Sweet.	25 Melon.
50 Porter.	100 Po'keepsie Russet.
25 Fall Pippin.	

For special localities, where they are known to do well, he would recommend Newtown Pippin, Esopus Spitzenberg, Northern Spy, Hawley and Swaar. Also as apples promising well: Hicks, Belle et Bonne, Jeffries, Drap d'Or, Mother, Summer Bellfleur, Vermont Strawberry, and Vermont Beauty.

The above lists refer to this vicinity, though most of the apples do well in all parts of the country. The best general information upon varieties adapted to different sections, will be found on page 147 of our last volume (May *Agriculturist*, 1862); and in the reports collected from the whole country as published in several numbers of volume XX (1861).

Grapes—Trellises—Strawberries.

INTERESTING TO GROWERS OF SMALL FRUITS.

Rev. J. Knox, of Pittsburg, Pa., whose extensive culture of strawberries perhaps entitles him to be called the "Strawberry King," is also pretty largely engaged in grape culture. We do not quite share his enthusiasm in regard to the Concord Grape, which he claims to be the grape for this country, but he confidently predicts that we shall have to come to it after the results of a few more years are seen. During his recent visit to the *Agriculturist* office we gathered some particulars concerning a grape trellis, which he devised and has extensively used, and his mode of growing grapes and strawberries together. The foundation for the trellis is made by setting locust, or other durable posts, at a distance of 12 feet apart. These posts, *a*, are $3\frac{1}{2}$ feet long, and are set $2\frac{1}{2}$ feet in the ground. To these are spiked uprights, *b*, made of hemlock scantling 3×4 inches, and 6 feet long. The horizontal strips, *c*, sawed out of pine stuff, are 1 inch thick, and 4 inches wide. Mr. Knox uses them 24 feet long, so as to reach across two sections of the trellis, but where it is more convenient, they may be made 12 feet in length. The slats, *d*, are of pine, $1 \times 1\frac{1}{4}$ inch, 8 feet long, and are fastened, 9 inches from center to center, to the horizontal strips, *c*, by a single 8d nail at each. The trellis may be put up at the time the vines are planted, or the posts may be set then, and the rest added as needed. The slats need not all be put on until the third year. Mr. Knox prefers to plant vines only one year old from the eye; these are cut back to a single bud, the shoot from which is tied up to a stake, and allowed to grow as long as it will; during Summer the laterals or branches are pinched off to one leaf. In the Fall this cane is cut back to two buds, which the next season is treated as before, and kept tied to stakes or to two slats upon the trellis, as is represented in the left-hand vine. At the close of the second season the vine has two strong canes, which are shortened to 3 feet each, and in the Spring of the third year are trained out horizontally to make arms, as in the right-hand vine. The wood formed the third year is trained to the slats, and afterward pruned upon the renewal or spur system, as may be desired. Mr. K. prefers the renewal plan, but deviates from it when necessary, to keep 48 square feet of trellis covered with the bearing wood of one vine. The trellises are placed 8 feet apart, and the intervening spaces are occupied by strawberries, which he finds do not interfere with the grapes, and are benefited by the shelter which the vines afford. At $2\frac{1}{2}$ feet from the grapes a row of strawberries is planted; this one is followed by three other rows, a foot apart, which will leave another space

of $2\frac{1}{2}$ feet to the next row of grapes, giving four rows of strawberries between each two rows of grapes. The two outside rows of strawberries are allowed to make runners, which root in the space left next the grapes, while the runners of the other rows, and all those from the outside rows which run in toward the other strawberry vines are carefully taken off. The runners which are left

to grow, furnish a supply of plants for market the first Fall after planting, and thus a paying crop is taken from the land the first year. The next year a crop of strawberries is obtained, as well as other vines from new runners. By pursuing this method, Mr. Knox makes the land produce returns every year, and thinks that by arranging in this way, the strawberries will pay for the whole expense of the grapes—purchasing the vines, preparing the soil, and cultivating until they come into bearing.

Propagating the Grape.

Mr. J. Borland, of Bucks Co., Penn., having been very successful in propagating the Delaware grape by grafting, the Fruit-Growers' Meeting requested him to communicate his method. Mr. B. very modestly disclaims any originality in the matter, and says that he was induced to try the plan from having seen it noticed in the *Agriculturist* for March, 1862. A set of specimens illustrating the process was sent, from which we have had engravings made that will enable our readers to easily understand the manner of working. The cions, which should be cut when the vine is quite dormant, have two buds to each: the lower end is cut wedge-shaped, with the lower bud at the base, or broad end, of the wedge, as shown in Fig. 1. The

Fig. 1.

cions should be of one-year-old wood, while the wood into which they are grafted may be two or more years old. A branch, which can be readily laid down, is selected and split quite through, at intervals of

every 18 inches or 2 feet, to receive the cions. In the specimen sent by Mr. Borland the grafts were inserted about one or two inches from

each joint. The wedge-shaped ends of the cions being inserted in the branch as in Fig. 2, it is then laid down and buried in the earth, leaving the upper bud of the cion just above the surface. Mr. B. prefers to do the grafting about the 20th of March, but it may be done at

Fig. 3.

any time before the sap starts. In the following Fall or Spring the branch containing the grafts may be taken up and cut off near the new vines, which will now be well rooted, and able to take care of themselves. Fig. 3 represents a vine which was grafted last Spring. This method has been very successful with the Delaware, which is difficult to propagate from cuttings in the ordinary way. It can hardly be called grafting, as the old stock is of no use after the first year. The union between the stocks and graft is very slight, but sufficient to afford sustenance until the cion makes roots of its own, which it does very freely. When the new plant is removed, the stocks may be cut off quite close to it, or even removed altogether. The plan is worthy of the attention of those who have vines of any inferior quality, and wish to replace them with choicer sorts. Mr. Borland is very successful in grafting the Delaware upon old roots. The vines are "cut off 6 or 8 inches under ground, split in four pieces, and the grafts inserted. If the grafts are likely to be pinched, put in wooden wedges, tie up with waxed cloth, and earth up within one inch of the top bud of the graft."

Late Pears Profitable.

We have this day (March 4th) seen two barrels of Vicar of Winkfield, and half a barrel of Glout Morceau pears in a fine state of preservation, with every indication that they will keep a month longer. They were raised by W. S. Carpenter in Westchester Co., N. Y., picked late, and packed in unwinnowed oats. They were then kept in a cool place, and are now in a common cellar in this city with apples and potatoes. Mr. Carpenter is eminently successful in keeping pears, and finds it pays well. He is now offered \$1.50 per dozen for his Glout Morceaux, and the Vicars would probably sell for \$20 per barrel. Such results indicate that it would be profitable to give more attention to winter pears. They can only be found on sale at a few of the fruit stands, at this season of the year, and bring enormous prices. Doubtless there is much yet to learn regarding the best method of keeping fruit, though there has been much light thrown upon the subject during the past few years. Let us have more light, and—more winter and spring pears. (P. S. March, 11th. The Vicars sold to day at \$35 per bbl.)

What is the Potato?

It has already been hinted on page 53 of the *Agriculturist* that it is not a root, as ordinarily supposed, but a kind of branch. We now propose to give some of the reasons for considering it a branch, without stopping to show how it is unlike a root. At first sight it appears to have little in common with the stem as we ordinarily see it, yet a careful comparison of the two, will perhaps discover resemblances which were not before noticed. Many persons suppose that botanists are chiefly engaged in giving hard names to plants, while the fact is they are mainly occupied in studying the plan upon which plants are made; they find that all the great variety which vegetation presents can be reduced to a few simple forms—the root, stem, and leaf, and wherever a part may be or whatever shape it may assume, the keen eye of the skillful botanist penetrates the disguise and finds out its real nature. The potato, being as unlike a branch as well can be, will serve to illustrate the manner in which these resemblances are traced out. In the first place the potato grows under ground. Every thing that grows beneath the surface is not a root, nor are roots always under ground, as every one who has hoed corn will have noticed. When we lay down a grape vine or a shrub, the layered portion is not a root, nor are the natural layers which rose bushes, and many other plants which spread in this way, make. The potato is the end of an underground branch, modified for a particular purpose, to serve which it becomes filled with starch and hence serves as an important article of food. Let us take for comparison a twig of an apple tree and see if it has anything in common with the potato. At this season the apple twig has no leaves, but the scars, or places, were they were, are plainly to be seen, and directly above these are the buds which will produce the branches of the next season—each scar being separated from the next by a length or joint of stem. Aside from the fact that the potato, as it grows under ground does not need to have strength and is not woody, but fleshy, we find that both have these peculiarities. The

buds on the apple stem are represented by the “eyes” in the potato, and branches proceed from both. The potato growing under ground has no use for leaves, but a little scale or wrinkle just under the eyes stands in place of them. These scales, which are more prominent in some varieties than in others, are best seen at the “seed end” of the potato. On page 53, the spiral arrangement of the eyes of the potato was noticed, and this can also be found on the apple twig. Perhaps the strongest proof that the potato is really a branch, is found in the fact that sometimes the above-ground branches become quite like the potato in size and shape and everything but color. We have seen instances in which every graduation could be traced between ordinary branches, having leaves, and fully developed potatoes without leaves. The engraving is from a drawing made some time ago by Mr. Ed. M. Prufman of St. Joseph Co., Mich., and represents one of these branches which grew about a foot from the ground. It will be seen that it is intermediate between a potato and a branch. It is short and fleshy like a potato but bears leaves, and these leaves come exactly in the place of the scales upon the potato.

Perennials for the Flower Garden.

Every garden should have a good stock of reliable herbaceous perennials, which as a class have been much neglected of late for the more popular and more expensive bedding plants. Once set out, these plants need no other care than lifting and dividing when the roots get too large. They may be planted as soon as the frost is out of the ground and will do all the better if the crowns are covered in winter with coarse stable manure. A friend of large experience has prepared at our request a list of 20 varieties which comprises a variety in color and time of blooming. To save answering inquiries we will say that we have none of these for sale, but they can be had at the principal nurseries.

Arabis alpina.—Flowers small, in clusters, pure white, six inches high; blooms in April. *Achillea Ptarmica, plena*.—Flowers double, pure white, 1 foot high. June. *Baptisia caerulea*.—Fine blue flowers; 2 feet high, May and June.—*Var. alba* with white flowers. *Campanula coronata*.—Flowers clear white, semi-double, abundant bloomer; 1 foot high, June and July. *Campanula grandiflora*.—Large deep blue flowers, 2 feet, May and June. *Clematis serratifolia erecta*.—Flowers white, in long clusters, 3 to 4 feet, May. *Clematis integrifolia*.—Flower large, dark blue, bordered with white; 2 feet, last of May and 1st of June. *Chelone barbata*.—Fiery scarlet, borne on a long stem, 4 feet, June and July. *Carnations* (hardy).—In varieties. *Dicentra spectabilis*, (often improperly called Dielytra).—Rosy crimson, one of the best border plants, 1 to 2 feet, May and June. *Delphinium formosum*.—Deep azure blue, with white center, 2 to 3 feet, June and July. *D. Sinensis*.—Bright blue, foliage quite distinct from the above, 2 feet, June. *D. Sinensis alba*.—Like the preceding but white flowers. *Geranium Alyssum*.—Flowers large, bluish purple, 8 inches, July. *Iris nana*.—Bluish purple, 6 inches, May. *Iberis Tenoriana*.—(Hardy perennial candytuft).—White, 8 inches, April to July. *Lychnis Chalcidonica plena*.—Double scarlet, 3 feet, June and July. *Phloxes* in variety. *Phlox verna*, a fine trailing species with large pink flowers, should be admitted in to the smallest collection. *Pentstemon Digitalis*.—White, slightly tinged with purple, 3 to 4 feet, July. *Spiraea Filipendula ple-*

no.—Flowers very double, pure white, 1 foot, May and June. *Spiraea Japonica*.—White, distinct and really beautiful, 1 foot, May. *Spiraea lobata plena*.—Fine red, strong grower, 2 feet, June. *Veronica spicata*.—Deep blue, 1 foot, June and July. *Veronica alba*, similar to preceding, but with pure white flowers.

THE HOUSEHOLD.

Cleaning Clocks—“Cooking Time.”

“Necessity” writing to the *Agriculturist* from Sand Beach, Mich., says: “Should any readers be situated as we are, in Huron Co., out of the reach of civilization and ‘clock tinkers,’ and their brass time pieces refuse to be time pieces, for want of cleaning, the following may be of use: Unscrew the metal from the case, and boil the wheel works half an hour or so in soap suds, and then five minutes in clean water, drying off quickly. This will clear out dust and hardened oil, and the clock will be ready for resuming its daily duties.” [As a last resort, this may answer well for clocks moved by weights. The boiling might injure the temper of the springs of those having this motive power, though perhaps not, and there can be no loss in experimenting with a clock that has ceased to be good for anything. A very thin coat of limpid oil, or even of fresh lard, if the oil be absent, should be brushed over the entire works with a feather, as soon as soon as dried from the water, to prevent the steel pinions from rusting. A very little oil stirred into the last cleaning hot water might answer.—ED.]

About Cloves and Allspice.

Cloves are produced by a tree which is a native of the Molucca Islands, and were like nutmegs a long time under the exclusive control of the Dutch government, who for many years would not allow the trees to grow upon any except the island of Amboyna, from whence the highest priced cloves still come. The tree is from 15 to 30 feet high, with large aromatic leaves and bunches of very fragrant flowers. The spice is the unopened flower-buds, which are beaten off by means of rods and then dried. The little ball at the top of the clove is the unexpanded petals; by softening the clove in hot water these can be carefully laid open by means of a pin. The main portion of the clove is what would be the fruit were it allowed to go on and ripen. Our word clove, comes from the French *clou*, a nail. That being the name by which the French call them on account of their resemblance to a little nail. They contain a good deal of volatile oil, upon which their value depends. This oil is sometimes extracted in part and the cloves afterwards sold. These can be told by their lighter color and by having the buttons or rounded portion broken off. Cloves readily

absorb a considerable amount of moisture, and it is the custom of large dealers to keep them in a rather damp place in order to make them weigh heavily and look fresh and plump. It is bad economy to buy cloves or any other spice in the ground state as, aside from the risk of adulteration, the oil is absorbed by the paper in which they are put up.

Allspice is from a tree, nearly related to the clove tree; it grows in the West Indies where it is largely cultivated for the spice, which in this instance is the fruit. The berries are gathered when green, for if allowed to remain on the tree until ripe they have an unpleasant flavor. It is also called Pimento, and Jamaica pepper. The name allspice was given because it was thought to have the flavor of cloves, cinnamon, and nutmegs combined.

Letter from a Housekeeper.

[The following letter we print for several reasons. It reveals some of the difficulties experienced, by those especially whose proper training for woman's sphere has been omitted. It is in this respect a fair sample of hundreds of letters we receive, and the writer and others will notice that more questions are propounded in this single letter than we could answer in an entire paper, while there are some queries that we can not answer at all, such for example, as how to "do up" linen like that bought ready made. Perhaps some of our fair readers can aid Mrs. Pry. We care not how many such letters are sent in—the more the better—for we like such plain, natural revelations of the difficulties experienced, and the wants of our readers, that our columns may be adapted to meet the necessities of the greatest number possible. Mrs. Pry will excuse us for making practical use of her "confidential letter," as we suppress her real name.—Ed.]

Washington Co., N. Y., March 3, 1863.

MR. EDITOR:—I have no ambition to see my name in print, so if you make any reference to my queries, call me Mrs. Pry, for this is a strictly confidential letter. I am a young housekeeper, in the capacity of a farmer's wife, and you will readily imagine I have experienced some trials, when I tell you that I never had the least training in the important department of housekeeping, not even in the city where I was reared, mainly—much less was I fitted for the domestic affairs devolving upon a farmer's wife. Oh! I often think I would give all my old shoes, and my new ones too, if I could only "keep house" as Mrs. so and so does, those who always do every thing properly, and at the right time. Then I should take pride in and enjoy my domestic duties. But the familiar adage, that "what man has done, man can do," has helped me through many any undertaking, and it will hereafter help in accomplishing much more than I am now capable of. The *American Agriculturist* has been a great help to me in many instances, with its hints in the household department. Somehow the recipes seem more valuable, and, to my unsophisticated judgment, appear more plainly expressed, and more sensible and practical than those I find in the professed "cook books," for these usually describe expensive fancy dishes and in larger proportions than we actual housekeepers dare venture upon with our small families, and in these latter days when economy should be practised. We like, it is true, to have something nice once in a while, by way of variety, but some how in following the cook books I get the expensive but not the nice. There are some housekeepers who seem to have the knack of always presenting before you the most simple food, invitingly, cooked just enough, and none too much. I am ambitious to acquire that "knack." Others get up a variety of expensive dishes, but each one is accompanied with an apology for its not being quite right.

Since I have been a housekeeper, I have often greatly wondered why it is that so many mothers suffer their daughters to grow up so ignorant of the very department they hope and expect them to assume charge of. I am not alone in this feeling, for I find others around me who acknowledge that they have actually shed tears over their own ignorance. You will smile, perhaps, when I tell you that as I look upon my two infant daughters, I often think how much I will do in their training to relieve them of future embarrassment.

Those soap recipes in the last *Agriculturist* came

in good time: I had previously understood (from the hired girl I believe I learned it,) that only half as much potash was required as of grease, and so in attempting to teach my new girl, I found that something was wrong, but could not tell what. Following the paper we added more potash and have it all right.—Last Summer I canned some stewed tomatoes, but owing to my own failure, or the cans (Bodine's) some of them proved defective. Before the preserving season arrives again, please give your plan.—As I said before, we like to have the good things sometimes, and though you may suggest that it is not very healthy, I would like good practical directions for a Fruit Cake, and for Pound Cake, of family size; also further hints for making and putting on icing; also to know what kind of instrument bakers use in putting on the ornaments; also the process of polishing linen shirts and collars as they are when we buy them new. I have understood that it was done by an iron specially constructed for the purpose, but have inquired in many places for such an iron, in vain.—Had I room I could tell you of many suggestions in the paper that have helped my husband in his business. We would gladly aid in extending the circulation of your paper, but that is not possible, as most of our neighbors take it already. But I have consumed too much of your valuable time already, so with many good wishes for your welfare, terrestrial and celestial, I will sink in to the silent Mrs. PRY.

P. S.—I have attempted some corrections in the above, to fit it for a critical editor's eye, but can not make it all right. I have written with one foot on the cradle, and constantly been repulsed to the many questions of the eldest little daughter, who sits beside me, watching my inkstand the meantime as if tempted to try some mischievous experiments with it. You can not know how to sympathize with me unless you have experienced the same trouble in writing. [Oh, yes we can; we rather enjoy a little flock of such troubles—sometimes at least.]

Shoeing a Family—Western Life.

[The following letter from Cedar Co., Iowa, may furnish a useful hint, while it will be interesting as giving an insight into the economy practised by the pioneers who build up for themselves homes in the far West. We know by early experience something of this. Those boys and girls who wear home-made shoes and patched garments, and are brought up to habits of labor and economy, away from the corrupting influences incident to cities, villages, and densely populated neighborhoods, will turn out the effective men and women.—Ed.]

To the Editor of the *American Agriculturist*:

In the January *American Agriculturist*, pages 21-2, you ask "if any one can tell how to keep children in any kind of shoes that will cost less than about a dollar a month for each youngster?"—I can. In 1860 I bought a pair of shoes for my oldest child, a girl of ten, that cost \$1.25, but did not last a month. This was hard, with so little money as we had; so I cast about to see what could be done. I found a neighbor making over his boot legs into shoes for his children, and acting upon the hint, I got a friend handy with tools to make me 7 lasts, one for each member of my family, paying him 10 cents each, (70 cents). I next procured paper patterns; bought a hammer, awls, pegs, and thread, for 65 cents—in all \$1.35. Bristles I stole from the hog's back; clamps rigged out of a 2x4 inch piece, and two staves. Went to work upon the old boot legs. First pair of shoes pegged so fast to the last as to be nearly ruined in getting them off, but experience taught me better next time. With more practice, I can now get up a shoe that a Massachusetts woman is not ashamed to wear. I reckoned the saving the first winter at \$14; outlay, as above, \$1.35. Most of the work was done evenings. Old boot legs wear better than new leather. Two pairs of shoes thus made have already worn over six months. How many thousands of pairs of boot legs are thrown away or burned each month, that might save as many dollars.

When all the old boots in your neighborhood are

used up, get a side of kip and a side of sole leather; carry them to a workman, tell him to cut you out a good pair of boots, and make them. He will do it for less than \$2, and you have leather enough left for from four to ten pairs of shoes, of all sizes, which, with a little care, you can use all up. Try it friends, first on old boots, and then on what you please. In my family there are four girls and three boys, four of whom go to school $1\frac{1}{2}$ miles. I go $3\frac{1}{2}$ miles to teach, and home every night. We are all wearing what I have made except my boots, and those I repair. A YANKEE IN IOWA.

To Strengthen Woolen Stockings.

Mrs. C. D. Ketchum, of Jackson Co., Wis., sends the following hint to the *American Agriculturist*: "In knitting common woolen socks and stockings, knit cotton thread in with the woolen yarn; the size of the thread to be governed by the size of the yarn. For very coarse socks, skein cotton will answer, but even in such socks, very fine spool cotton will add greatly to their durability. In old stockings, I have found every stitch of the cotton perfect after the wool was entirely worn away. The thread prevents the pulling and breaking of the tender yarn." [Query.—As cotton thread is now so costly, would not linen thread answer an equally good purpose, and even be better at any time? The above plan may be old to others, as Mrs. K. suggests, but it is new to us, and appears to be a good one.—Ed.]

Coffee Substitutes—Another.

To the lover of strong, pure coffee, no substitute can be offered that will exactly fill its place. But there are several preparations which may be used as drink, and that answer very well where the milk or cream and sugar are the most desirable parts of the ingredients. Boiled milk, (which is always better than raw milk, for tea as well as coffee,) if well sweetened and creamed, may be flavored with a variety of essences or compounds to suit the taste of different persons, according to habit. Dandelion root is considerably used now, but it is a medicinal root, and should be reserved to use only as medicine. Chicory root burned approaches most nearly in flavor and effects to the genuine coffee, but it is not a safe drink. Continued free use of chicory will seriously affect the nerves, the digestive organs, and ultimately the whole system. We have accounts of the worst consequences resulting to chicory drinkers in Germany—quite equalling those produced by alcoholic liquors drunk to excess.

Rye, bread, corn, corn meal, barley, peas, etc., have each their advocates, and they answer a good purpose where the taste has not been confirmed for genuine coffee. Just now there are a multitude of manufacturers of "Rye Coffee," "Barley Coffee," "Dandelion Coffee," etc., and each one seems to be doing a good business. They get almost everybody to try one parcel, and this alone makes a large business. We have examined several of these compounds, some of them recommended quite strongly by those who have purchased and tried them. A careful analysis of some of the most popular "rye coffees," and "barley coffees" so called, show that they contain disguised chicory, and that they are flavored with burnt sugar. Any one using a home-made coffee of rye, barley, etc., will find a material improvement in the flavor if they smear the grain before burning with a little syrup made with sugar and water.

The best home-made coffee substitute, among all the numerous specimens recently sent to the *Agriculturist* office by subscribers and others, is a sample forwarded by Mr. Eleazer Latham, of Suffolk Co., N. Y., which he calls "Long Island Coffee." It yields a quite pleasant-flavored drink, especially when used—as we always use coffee—with a large amount of boiled milk, cream, and sugar *q. s.* The directions furnished by Mr. L. are to take coarse fresh ground WHEAT BRAN, sifted clean from flour and fine particles of bran or middlings (literally

wheat shells,) and moisten two pounds of it with about a half pint of good molasses mixed with the same amount of water. Then roast slowly in a pan until well browned. He adds the suggestion, which we think a good one, that the flavor will be improved by using sugar instead of molasses; that is, moisten the bran with sugar syrup. For use, take about double the quantity that would be required of genuine coffee. Some chicory or real coffee may be added, when a less quantity will be needed. Bran is cheap, about a cent a pound, and there is a good deal of "nourishment" in it, as well as a peculiar oil, that when roasted has an agreeable flavor. Indeed, it is the skin or shell of grain, as rye, barley, etc., that gives the chief flavor to the liquids made from them; the inner portion is mainly starch, which, when burned brown, is similar to charcoal, or the same as burned bread coffee.

Judging from several trials of the box kindly forwarded (express paid) by Mr. Latham, we think he has done good service to those desiring a palatable, cheap, and safe substitute for coffee. His suggestions about using sugar instead of molasses, is worth noting, as we detect a little of the disagreeable flavor of the molasses in the sample. We recommend the "Long Island Coffee," to general use, at least until something better is found. Several trials may be required to get the right proportion of sugar, and the proper degree of parching or roasting. A little overburning of even a small part of a batch, may render the whole bitter or disagreeable, the same as is the case with the real coffee.

What Shall I do with the Rats?

To the Editor of the American Agriculturist.

I come to you for help. First I will state my case. I am living in the city, and I find even the rats congregate there two. They have taken possession of a house next door to me, and, having dispossessed the occupants and eaten up every thing obtainable, they come upon me in hungry swarms. They have undermined the hearth, gnawed through the floor and wainscoting and even made holes through the plaster ceiling. The question now is, shall I decamp and leave them in possession or, as my house is my castle, shall I defend it, and if so, how? I have had two steel traps set, and manage to get a young inexperienced rat in occasionally, but the old settlers wink at me from their hiding places, and even contrive to get the tempting morsels from the trencher, and escape with a whole skin. I suspect they dig through the bran under the trap, spring it from beneath and coolly walk off with the cheese or meat. They appear to be on the most friendly terms with the cat, as much so as those composing the happy family at Barnums. I do not like to poison them, fearing they will die in the walls and create a stench. Now Mr. Editor, is there not some way of getting rid of the "varmints" without leaving their dead carcasses to breed disease in the walls, or must I make the best terms I can with them and be at peace? TABITHA.

[REPLY.—Tabitha comes to a poor source for aid, though we can abundantly sympathize with her. As we have a good many seeds about our office, house, barn, etc., the rats are of course very neighborly. The terrier keeps them within moderate bounds at the outhouses, and the cats still maintain their supremacy at the house and office rooms, but what can a cat do inside of the narrow retreats of rats and mice? We have tried traps of almost all kinds, but for every rat killed, a dozen more came to the funeral. Just now, however, we are having a respite. Two months since we bought a large box of patent "phosphorous salve" such as most druggists offer for sale as a rat destroyer. It was spread upon a large slice of bread which was cut into twenty pieces and put around where the rats "most did congregate." The pieces were all gone in the morning. The rations were dealt out again, and about half consumed or earried off. A third supply was left untouched, and the rats and mice disappeared one by one, until all were gone. Whether they are absent at a "convention" to return in ten-fold numbers we can not yet tell. A few years ago

we tried a similar phosphorous salve, and was rid of rats for six months, after which time they returned, and all the salve we could buy did not trouble them. Having occasion to move, we left them in possession. This may be the result now, but six months relief is worth the cost of at least as many boxes of salve.—Ed.]

A Humbug "Healing Association."

A good many inquiries have been received, respecting a so-called "People's Healing Association," advertising from this city; and from what we can learn, this swindle is getting considerable patronage, though not from the readers of the *American Agriculturist*, who have been forewarned so frequently that they forward the circulars and letters to us by way of amusement. The fellow at the bottom of this, by means of advertisements and circulars, gets a silly, or nervous class of persons to forward a description of their "case" to him, and then sends back a quasi letter like the following. (The letter is a lithograph. It seems that he has too much patronage to admit of writing to his "patients," and so he prints letters off in close imitation of actual writing. Of course the directions fit each case, just as well as if written out for it—an easy way of earning \$8 for an adult, and \$3 for a child. A printed circular, with this, offers more powders for more Dollars, if the first don't cure.)

[Literal Copy] New-York City, N. Y. Febr. 18th, 1863.

Respected friend.—Your kind letter is received and your case fully examined. We find it a very bad one, indeed much more critical than you have yet believed, and if not speedily arrested you must die from its ravages.

We find the digestive organs blood liver lungs &c are in a bad state chemically and functionally causing a condition of much danger.

You may doubtless feel that death is not so near, and that you will escape. But believe us kind mortal, we know for a certainty that your doom is sealed and a fatal termination will take place before you are aware.—There is yet hope.—We find the combination of symptoms such that we not only believe, but know that you can be cured by a prompt and skillful combination of our new Remedies. As friends we beg you not to delay & thus die a horrid death when you can be saved. Send us by mail eight dollars and the remedies will be immediately sent. May God bless you and the means for your cure and happiness. In the mean time, knowing your condition—the danger of a fatal issue and the risk of a delay, we take the liberty to send in this a Remedy for you to use till you have time to send and obtain of us the full combination. This will prepare the system for the others and prevent any change for the worse for a few days. We do this for your good & at our expense, for we wish to do by you as we would have you do by us, under the same condition. Again we say do not delay.

Respectfully Yours,
A. ACKLEY THURBER.
P. S. We can speedily cure your child. Send \$3 dollars for him. A. A. T.

My Bottled Fruits.

To the Editor of the American Agriculturist.

I was a careful reader of your directions for putting up fruits last Summer, and experimented not a little myself with the following results: I have discarded tin cans entirely of late years, as dangerous, and use only glass and earthenware. The most of my fruits were put up in Potter & Bodine's glass bottles having a rubber ring fastened to the tin cover, and an iron clamp, which, by turning, secures the cover on tightly. These all kept well, and for simplicity, ease of putting up, and cheapness, when compared with other patents, I give them the preference. Several new forms were used, but with indifferent success, though I will not entirely condemn them yet. I tried the regular black wine, or junk bottles, and followed your directions on page 215 July *Agriculturist*, putting strawberries, grapes, etc., (the last a nice thing for raisins in minee pies during the Winter,) in the bottles, filling them with cold water, driving the soft corks in tight and tying them firmly. They were then put in cold water, set on the stove, and boiled for perhaps half an hour. I noticed the steam forced its way through the corks, so I dipped them in melted wax and laid them away. They kept well, and we think the strawberry flavor more perfect than in the others. Of course they were sugared when eaten.

I kept cherries and other fruit very well in stone jars, pouring them in while boiling hot, with a little sugar, then covering with cloth before laying

on the lid, and pouring melted cement around its edges. They opened well. The jars may hold one half to one gallon each. This is the cheapest method I have tried. I also kept tomatoes in glass bottles with nothing but cemented cloth tied securely over the mouths. The cloth was strong muslin, coated on both sides with cement, and when it shrunk in cooling, more cement was poured on. They came out fresh and good. I used in addition, the patty pan arrangement you originated, and with uniform success. The cement used is the same as formerly described in the *Agriculturist*, viz.: about 14 to 16 ounces of common resin and 1 ounce of tallow, melted and stirred together.

Brooklyn, March 10th, 1863.

HOUSEKEEPER.

Hints on Cooking, etc.

Railroad Cake.—Contributed by Mrs. C. A. Williams, Litchfield Co., Conn. Mix 1 cup of white sugar, 1 of sifted flour, 3 beaten eggs, 2 tablespoonfuls milk, a piece of butter the size of a hen's egg, 1 teaspoonful cream tartar, $\frac{1}{2}$ teaspoonful soda, and $\frac{1}{2}$ teaspoonful extract of lemon.

Soda Biscuit.—Contributed to the *American Agriculturist* by a subscriber at Emerald Grove, Wis. Take 1 pt. sweet cream, 1 teaspoonful soda, 2 of cream tartar, a little salt, and flour sufficient to mix the ingredients quite soft. Bake in a quick oven.

Apple Pudding: by the same. Fill a pudding dish with acid apples pared and quartered. Cover them with a thick crust, made as directed for soda biscuit, and bake half an hour; serve with sugar and cream.

Corn Bread Coffee.—Contributed to the *American Agriculturist* by Anna Woodruff, Westchester Co., N. Y. Make a simple corn bread, of meal, salt and water. Mix the meal, either yellow or white, with just water enough to wet it; the water may be either warm or cold, then bake it to a dark brown, or as dark as real coffee when burned. A piece of the bread as large as one's hand, will make coffee several times. Pour water on the bread unbroken, and boil an hour or so. Add more water for another time. [A rather weak liquid.—Ed.]

Economical Wheat Bread.—A subscriber to the *Agriculturist* at Seltzer's Store, Pa., sends the following directions for making good bread: Take 2 qts. of small potatoes, wash thoroughly, boil soft, and mash. Then pour 5 pints of warm water on the potatoes, stir them up and strain through a colander; this will separate the potato from the skin. Add flour until it becomes very stiff; stir in 1 pt. of yeast, and 1 tablespoonful of salt. Let it rise until light, or three or four hours, then add flour, and knead well. Set it to rise again; when light, knead in loaves, and when sufficiently light, place in the oven and bake 1 hour. This will make 3 good sized loaves.

Potato Yeast.—Contributed by Anna Woodruff, Westchester Co., N. Y. Boil twelve peeled potatoes, and mash them well. Add a quart of the water they were boiled in, while hot, and a cup of sugar. When cool, add a quart of cold water, and a half pint of fresh yeast. Let it stand in a warm place twelve hours, after that shut it up tightly, and keep it in a cool place. It will rise quickly and make delightful bread. [We would say do not add the water the potatoes were boiled in.—Ed.]

Boiled Wheat.—Mrs. D. Tuttle, Mendocina Co., Cal., writes that boiled wheat as described in the *Agriculturist*, page 23, (Jan. No.) forms a frequent dish in that vicinity, which is more than twenty miles from the nearest grist-mill. She says it is improved by first boiling it in weak lye to separate the hulls. After this, wash it with cold water several times, then cook for the table. It is considered nearly or quite equal to rice.

To Boil Eggs.—M. B., Blainsville, Pa., writes that the best way to boil eggs is to place them in cold water and set them over the fire. In this manner the center of the egg will cook as soon as the outer part. If they are preferred soft, the water should not come to a boiling point.

FLYING FOXES OF CEYLON.

The Editor with His Young Readers.

Our young friends are doubtless familiar with the appearance of the common bat. It may be seen on almost any summer evening flitting about in pursuit of insects, sometimes entering dwellings. They are friends to man, and none but uninformed persons would think of killing them. They destroy multitudes of millers and other insects, which would otherwise spoil fruits and vegetables. The curious creatures represented in the engraving are of the bat family. They are so large that they have been named flying foxes. Specimens of them were brought to London a few years since, from which our sketch was made. A writer says of them:

"There are more singular inhabitants of Ceylon trees than monkeys. The flying foxes hang from them like fruit. The flight of these creatures is directed by means of a membrane attached to the inner side of each of the hind legs, and kept distended at the lower extremity by a projecting bone, just as a fore-and-aft sail is distended by a 'gaff.' Over the entire surface of the thin membrane of which they are formed, sentient nerves of the utmost delicacy are distributed, by means of which the animal is enabled during the darkness to direct its motions with security, avoiding objects against contact with which, at such times, its eyes and other senses would be insufficient to protect it. By day they suspend themselves from the highest branches of the silk-cotton trees, hanging by the claws of the hind legs, with the head turned upward, and pressing the chin against the breast. At sunset, taking wing, they hover with a murmuring sound, occasioned by the beating of their broad, membranous wings, around the fruit trees, on which they feed until morning, when they resume their pensive attitude as before. They hang in such prodigious numbers that the branches often give way beneath their accumulated weight. They fly in clouds as thick as bees or midges. When at rest or asleep, the disposition of the limbs of the flying fox is most curious. At such times it suspends itself by one foot only, bringing the other

close to its side, and thus it is enabled to wrap itself in the ample folds of its wings, which envelope it like a mantle, leaving only its upturned head uncovered. Its fur is thus protected from damp and rain, and, to some extent, its body is sheltered from the sun. As it collects its food by means of its mouth, either when on the wing or when suspended within reach of it, the flying-fox is always more or less liable to have the spoil wrested from it by its intrusive companions, before it can make good its way to some secure retreat in which to devour it unmolested. In such conflicts they bite viciously, tear each other with their hooks, and scream incessantly, until, taking to flight, the persecuted one reaches some place of safety, where he hangs by one foot, and grasping the fruit he has secured in the claws and opposable thumb of the other, he hastily reduces it to lumps, with which he stuffs his cheek-pouches until they become distended like those of a monkey; then, suspending in safety, he commences to chew and suck the juices, rejecting the refuse with his tongue."

About Blue Birds.

A correspondent, "A. H. G.," Rondout, N. Y., writes for the boys and girls of the *American Agriculturist* the following interesting facts: "I am not aware whether it is generally known, that our useful and beautiful blue bird is more or less lacking in that instinct that belongs to other members of the feathered tribe. They are domestic little creatures, and disposed to build as near as possible to the habitations of man. Like the wren—with whom they are never on good terms—the bird house, or wood shed, or hollow apple tree, in the door yard, are their favorite haunts. But when these are not available their ignorance in selecting a place, is somewhat remarkable. They appear to have but little idea of the space that they require for their nesting operations, and many hundreds must yearly fall victims to this singular ignorance. The first instance of this that came under my notice was several years ago. A neighbor was standing upon his piazza, in early Spring, when he heard something fluttering, apparently inside the pillar against which he was leaning. It was one of those hollow posts—put up more for ornament than use—about five inches square upon the inside. On examining the post he found a large knot hole just under the eave of the piazza. This

immediately led him to saw off one side of the pillar about eight inches above the floor, and having pried off the piece, imagine his surprise to see a blue bird fly out, and to find within two only recently dead, with the skeletons of more than a dozen others—the accumulation of several years. Another instance of a similar character, occurred in the stove pipe of a small country church. The pipe was raised about eight or ten feet above the roof and covered with a 'smokejack.' In the Fall of the year when the Sexton came to examine the flue, preparatory to putting up the stove, he counted seven blue birds, that were found just where it joined the pipe. So emaciated had they become before dying, that scarcely a feather except those of the wings was ruffled. They had dried with almost as much perfection as though prepared by the taxidermist. One other instance, only not attended with so great fatality, occurred in a wood-shed.—A piece of pipe several feet in length was standing on the stove, in a corner of the building, near an open window. When the stove came into requisition, here again, we found a blue bird in the flue—in a state of almost perfect preservation. The ends of the wings in every instance were the only parts that had suffered. They were worn quite up into the shaft of the feathers—a proof of the efforts that the little creatures had made to rise, and failed from want of sufficient room to spread their wings. Care should be taken to prevent such occurrences, by providing houses of larger dimensions than 'wren's nests,' where the blue bird can find a place of comfort and security to build. They are worth preserving in a garden. The insects that they destroy as well as the beauty of their color and the domestic character of their lives and song, should place them among the farmer's especial favorites."

Confiding Birds—Pleasing Incident.

J. E. Hardisty, Jerusalem Mills, Harford County, Maryland, writes to the *American Agriculturist* as follows: "Last Summer, about the 1st of August, a pair of the wren family, called here the 'woods wren,' were observed near our kitchen door, upon an apple-tree, making an unusual noise, seemingly in great distress. The cause was soon discovered: one of their young ones had just fallen a prey to the cat. Two or three days after, apparently the same birds were frequently seen flying in and out of the second-story windows, and, to our surprise, we found that they had gathered a wad of dried grass as large as a child's head, upon the top of the wardrobe, where was a space about six inches high. The nest was neatly formed, and lined with feathers, but not so carefully as is done by common house wrens. At first the birds were a little shy of us, but soon learned to disregard our presence. Our little folks, four in number, were successively lifted up to see, first, the nest; secondly, the bird on the nest; thirdly, the young birds, two in number. Nothing could exceed the joy of the children as they gazed again and again upon the confiding little creatures, nor was our own pleasure much less. About the 1st of September, my wife on going up stairs found the young birds hopping about the room; one of them flew up and clung to her breast, and remained there for some time, looking about and up into her face with the greatest confidence, while she moved about from room to room attending to her duties. By night they had disappeared, and have not since been seen, though we now and then hear their pleasant notes: 'Te-heugh-heugh, Te-heugh-Teaugh, Te-heuit,'—which in the Winter, for they remain with us all Winter, is changed to 'Tittle-lu, Tittle-lu, Tittle-lu.' They warble other notes which our language cannot express. They are a little larger than the common house wren, with long tail, comparatively large broad head, with a whitish streak curved over the eyes; back, light brown; breast, bluish white. Their movements are very similar to those of the house wren."

A Mysterious Black Cat.

A lady of the writer's acquaintance was one evening sitting alone in a room from which a door opened into a long dark hall. As she chanced to look in that direction, she was somewhat startled to see what appeared to be a large black cat sitting upon the hall stairs. There were two brightly gleaming eyes glaring upon her in a manner that made her feel rather uncomfortable, especially as she owned no cat, and it must be a strange animal. "Scat," she exclaimed, stamping on the floor. It did not move. "Scat," once more, with a louder stamp. But still it remained. She drew off her shoe, and with another "scat" threw it directly at the object, but there it sat as before. Though somewhat startled, the lady was no coward, and taking the lamp she went directly to the mysterious animal and found she had been trying to drive away the ends of two bright brass stair rods, from which the light had been reflected, presenting the appearance of two glittering eyes: the shadow of the stair to an excited imagination might easily represent the body of a black cat.—How many ghost-fears originate similarly.

The Boys and Girls' Garden—No. 1.

An unusual number of business items has crowded out a share of the space intended for the young people, but perhaps there is room for all that is necessary so early in the season. As hinted last month, we intend to give some plain and familiar Talks about plants and the way in which they grow, which will be both interesting and useful to our young readers, and perhaps to older ones also. While we shall use engravings to explain what we write, it will be much better to have the living plant directly before us to talk from, and before our readers also, and we advise all those who wish to follow these lessons to put in seeds of the plants we have selected to illustrate them. The seeds are: Flax; Sweet Pea; Muskmelon; Tomato; Morning Glory; Four O'clock, and Oats. If more convenient, the common Pea and Cucumber or Squash may be planted in place of Sweet Pea and Muskmelon. All these seeds can be procured by every one. They should be planted in a bed in the garden, where they can be watched all summer. It is best not to put the seed into the ground until it becomes dry and warm weather. So look out for the seeds now, and be ready to meet us for a Garden Talk next month.

New Puzzles to be Answered.

No. 35. *Illustrated Rebus.* A most excellent rule.
No. 36. *Problem.*—Suppose a clock to have six hands, which go around respectively in 1, 6, 12, 18, 24, and 30 hours, and that they are together at 12 o'clock, April 1st; when will they next be together.

Answers to Puzzles and Problems in March No. (page 89). No. 31. *Illustrated Rebus.*—F ear toe doe vil if you wood be bray v. That is: "Fear to do evil if you would be brave."—No. 32. *Illustrated Rebus.*—Well bee gun eye S half done; or "Well begun is half done."—No. 33. *Mathematical Problem.* Answer 42 feet.—No. 34. *Word Question.* Answer: Faceliously, or abstemiously. N. B.—By an oversight, no answer was given to the *Illustrated Rebus* on page 57. (Feb. No.) It reads Be shoe-er ewe r rite before ewe-fight; that is: "Be sure you're right before you fight."

Crowded Out.—A good many pleasing items, problems, and a host of names of those sending in answers.—We expect to find room for them next month.

To Sunday School Teachers and Others.

The Book of "Lessons for every Sunday in the Year," has met with a success far beyond our anticipation. The edition of five thousand copies published at the office of the *Agriculturist*, which it was supposed would last a year at least, was soon exhausted, and another large edition printed. This is exclusive of the great numbers printed and sold by others. The many letters from Superintendents, Teachers, and others, commending it in the highest terms, are satisfactory evidence of its value. These questions and the accompanying lessons were originally prepared for our own school, without any thought of making a book, until repeated calls from others for copies, seemed to make it necessary. We shall continue to supply the work at 10 cents per copy, and as this barely covers the cost, the price is the same by the hundred or thousand. If to go by mail, the postage to be prepaid, is 4 cents for a single one; 3½ cents per copy on two to nine; and 3 cents each, where ten or more are sent in a single package. Over 1,500 miles, the postage is double these rates. The following is one of the many notices of the book which have appeared.

From the *Sunday School Times* (Philadelphia,) March 14.

"A NEW QUESTION BOOK.—We have just been examining a little book published by Orange Judd, (of New-York City,) called "*Lessons for Every Sunday in the Year*," and have risen from the examination with a feeling of thankfulness that such a book has been made. We have never seen a Question Book containing so many conveniences and advantages as this, so many excellences, both positive and negative. Mr. Judd is a life-long Sabbath-school man, and this book has been the fruit of the experience of himself and some of his friends in trying to meet the practical wants of the Sabbath-school. Like all good text books, it has grown out of actual necessities and experience; it is a growth rather than a work. We advise every Superintendent to send at once for a copy."

The Markets.

AMERICAN AGRICULTURIST OFFICE.
New-York, Thursday Morning, March 19, 1863.

1. TRANSACTIONS AT THE NEW-YORK MARKETS.

1863	514,740	3,156,890	1,398,051	59,100		96,382	
1862	619,675	2,091,731	2,712,301	305,005		6,408	

The above tables show at a glance the volume of business in Breadstuffs, and the figures below show the present prices and their changes. Prices of Breadstuffs, Provisions, etc., have gone up and down with the premium on gold, and their consequent variable value for export. Wool is in great demand and still advancing in price.

The Live Stock Markets are unusually active in this city, and prices have advanced one cent per lb. on beef within a month. The receipts of beef cattle have averaged 4,383 per week, but the taking out of 300 to 500 each week by buyers for the government, has left a light supply for butchers. Good animals now sell for prices equivalent to 10c. @ 11c. per lb. for the dressed carcass, and common to good stock at 8c. @ 9c. Sheep are higher than ever before, owing to the great advance on wool. They are now selling at prices equivalent to 9c. @ 10c. per lb. live weight. The whole of large lots have been sold out at an average of \$8.50 to \$9. per head. Live Hogs are in good demand and are selling at 6c. to 6½c. per lb. live weight for corn-fed and 5½c. @ 5½c. for still fed hogs.

FLOWER SEEDS BY MAIL.—The subscriber raises about one hundred kinds of Flower Seeds, selected from over one thousand varieties, of the most showy and attractive. He will furnish, neatly put up, any 33 kinds on the list for \$1, and send by mail, with postage prepaid.
G. R. GARRETSON, Flushing, N. Y.

ASPARAGUS ROOTS, of the best quality, two and three years old, at 40 cts. per 100, or \$3.50 per 1000, including packing. Can be sent any distance.

New-York State Agricultural Society,
Rochester Fair, 1862.

I hereby certify that JAMES PYLE, of New-York, was awarded a special prize at the State Fair at Rochester on his O. K. Soap, Dietetic Salcratus, Cream Tartar, Baking Soda, and various other articles of exceeding great merit—and the Executive Committee of the Society give special commendation for the great excellence of the articles exhibited.

In witness whereof I have hereunto subscribed my name, and affixed the official seal of the Society.

{ L. S. } B. P. JOHNSON, Secretary.

Great International Agricultural

Exhibition,

TO BE HELD AT

Hamburg, Germany, in July, 1863.

The attention of Agriculturists, Growers of Stock, and Manufacturers of Agricultural Implements, machinery, and others interested in Agricultural Products, is called to this Exhibition, which will probably exceed in interest and magnitude any Fair of the kind ever held.

Every facility will be afforded for the cheap transportation of all contributions to the Exhibition, as well as to the delegates from the several State Societies, and others connected with the Exhibition.

All applications for entries must be made to the only authorized Agents undersigned, before the fifteenth day of April next, who will furnish programmes and any information required.

Rhubarb.

Myatt's Linnaeus, \$1.00 per dozen, \$2.50 per hundred, \$15.00 per thousand.

J. KNOX,

Box 155, Pittsburgh, Pa.

Genuine Tree Cotton Seed.

A limited quantity of the above seed can now be obtained, if applied for soon, of

EDWARD TATNALL, Jr.,

Brandywine Nurseries, Wilmington, Delaware.

This seed was procured at considerable expense by William Ferris, of the above city, from the mountain regions of South America, having been conveyed thence by mule, "seven days journey," to Guayaquil, where this gentleman resided nearly three years, and made himself acquainted with the fact that this cotton thrives, and is cultivated on the elevated lands of the Andes, of which it is a native. His object was to introduce it into our Northern and Western States, believing if it would stand their climate (and where it now grows, it is frequently covered with snow and ice) it would prove a source of great interest and profit to the people of those States.

As seed represented to be that of the tree cotton has been palmed off on the public during the past year, this is WARRANTED to be the genuine article, and will be forwarded by mail, free of postage, at the following rates remitted in current funds with the order: 25 for \$1.00; 60 for \$2.00; 110 for \$3.00; 200 for \$5.00; 500 for \$10.00.

Clubs of 5 or 10 supplied at the latter rates if sent under one envelope. Should be placed by 1st to 10th of May. In sending orders give the Post Office, County, and State.

New Japan Honeysuckle.

Lonicera brachypoda aures reticulatis.

Parsons & Co., Flushing, N. Y.,

offer this beautiful plant at one dollar each.

The leaves are green, with a bright golden reticulation, giving with its foliage during the whole season an effect surpassing that of flowers which bloom only for a week or two.

RASPBERRIES.

Brinkle's Orange and Franconia, 75 cents per dozen, \$3 per 100; \$20 per 1000.

Fastloff, River's Large Fruited Monthly, Kneivitt's Giant, Hudson River Antwerp, Red and Yellow Antwerp, Allen's Hardy, Improved Black Cap, &c., 50 cts. per doz. \$2 per 100; \$15 per 1000.

Hornet, Pilate, Imperial, Souchett and Toilet, \$2 per dozen, \$10 per 100.

Blackberries.

New-Rochelle, Dorchester and Newman's Thornless, 75 cts. per dozen; \$3 per 100; \$20 per 1000.

We will furnish 100 each of the above three kinds for \$7.50. For prices of Select Lists, see our Circular.

J. KNOX,

Box 155, Pittsburgh, Pa.

At \$18.00 per thousand,

For sale by KING & MURRAY, Flushing, L. I., near New-York.

Strawberry Plants.

We have taken special pains to procure and preserve our varieties true to name. We cultivate our plants with the same care we do our fruit, and all sent out by us are not only of the best quality, but we guarantee them to be genuine. We offer the following at 35 cts. per doz. \$1 per 100; \$5 per 1000. Alpine Wood, white and red, Boston Pine, (same as Bartlett,) Brighton Pine, Baltimore Searlet, Burr's New Pine, Cutter's Seedling, Downer, Hovey, Hooker, Jenny Lind, McAvoy's Superior, Moyanensing, Wilson's Albany, and many others.

The following at 50 cts. per doz.; \$1 per 100; \$7.50 per 1000.

Duc de Brabant, Jessie Read, Nimrod, Trollope's Victoria, Triomphe de Gand, Vicomtesse Hericart de Thury, &c.

The following at 50 cts. per doz.; \$2 per 100; \$10 per 1000. Alpine Bush, white and red, British Queen, Bicton Pine, Georgia Mammoth, &c.

The following at 50 cts. per doz.; \$3 per 100; \$5 per 200; \$20 per 1000.

Golden Seeded, Fillmore, Kitley's Goliath, Princess Royal, &c.

Plants by Mail.

We will not send hereafter less than one dollar's worth of plants by mail, nor less than one dozen of any one kind, and in all cases at the price per dozen, except as designated below:

For \$1 we will send one dozen each of any three kinds offered at 35 cents per dozen. For \$2 we will send one dozen each of Triomphe de Gand, Fillmore, Trollope's Victoria, Wilson's Albany and Burr's New Pine. These five kinds embrace the different seasons of ripening, and are all favorites with us.

For prices of SELECT LISTS, see our Circular.

J. KNOX.

Box 155, Pittsburgh, Pa.

Russell's Strawberry.

This great Strawberry, combining all the good qualities of "Longworth's Prolific," and McAvoy's Superior, added to enormous size, possesses all the properties to make it the best Strawberry yet known, after six years' trial, being the largest and most prolific bearer, with an exceeding rich aroma—full of vinous juice, and for deliciousness unsurpassed—very hardy in its growth, enduring severe frost. It is not only a pistillate but a staminate.

JOHN J. THOMAS, editor of the Country Gentleman, Albany, who personally examined the beds in bearing, says, July 3, 1862—"It appears to come up fully to all that is said in its favor. On comparing it with the Wilson, the Russell was found to be, so far as we could judge, even more productive than that famed prolific variety, about equally firm in flesh, nearly double in size, and greatly superior in flavor. If its good qualities are maintained after it has been fully tried in different localities, it will not be surpassed, and perhaps not equalled by any other sort."

Fine Plants now offered at \$3.00 per dozen, Cash to accompany orders. Address GEO. CLAPP, Auburn, N. Y., March 2, 1863.

New and Splendid Varieties of Strawberries.

RUSSELL'S GREAT PROLIFIC. This is believed to be the largest and best Strawberry ever introduced. Berries over six inches in circumference, very productive and of the finest flavor. Price \$3 per dozen.

The following three varieties are the prize berries of Europe for 1862. They are of enormous size, weighing from one to two ounces each.

Empress Eugenie, Margarine, Princess Frederick William, Price \$2 per dozen.

La Constante, Oscar, Victory, Wizard of the North, Wonder, Prince of Wales, Filbert Pine, Crimson Queen, Bona de St. Julien, and Honneur de Belgique, at 75 cts. per dozen, or the ten varieties for \$5.

These are selected from over 100 varieties, and are believed to be of great excellence.

Great Austin, Triomphe de Gand, Bartlett, Downers Prolific, and Pyramidal Chili, at \$1 per 100, or \$6 per 1000.

All orders addressed to W. M. S. CARPENTER, 329 Greenwich-st., New-York.

GET THE BEST STRAWBERRIES.

The most productive are Wilson's and Downer's, Price 75 cts. per 100, \$5 per 1000.

The largest and handsomest is Triomphe de Gand, Price, \$1 per 100, \$5 per 1000.

The richest and best flavored is Bartlett and Ward's Favorite, price \$1 per 100, \$7 per 1000.

Other varieties, with a good stock of Currants, Raspberries, Grapes, and Blackberries, at equally low rates. Address E. WILLIAMS, Montclair P. O., West Bloomfield, N. J.

1,000,000 Strawberry Plants for SALE.

The Great Austin or Shaker Seedling, at \$5 per 1000. Triomphe de Gand and Wilson's Albany at \$3 per 1000. Hovey Seedling and Ladyfinger variety, at \$3 per 1000.

JOHN S. COLLINS, Moorestown, Burlington Co., N. J.

CATALOGUES GRATIS.

Brackett's Seedling Grape.

Price \$3 each.

Parsons & Co., Flushing, N. Y.,

Offer this fine new grape, the produce of Union Vineyard, crossed with a foreign variety. It ripens about Sept. 10th.

The report of the Massachusetts Hort. Society thus describes it:

"It was a large, round, black Grape, heavy bloom, large bunches, thin skin, little or no pulp, juicy, sweet, and very vinous.—Those of the Committee who tasted of it, formed the highest opinion of its value, and it seemed to them the best and by far the most promising new hardy grape that had been brought to their notice."

FOREIGN GRAPES FOR VINERIES.

We offer this Spring a large stock of Foreign Grapes, well grown and well ripened plants in pots, embracing the old standard sorts, and the following superior new varieties:

Austrian Muscat,	Lady Downs,
Bidwell's Seedling,	Muscat Ottonel,
Bowood Muscat,	Muscat St. Laurent,
Buckland's Sweetwater,	Muscat Hamburg,
Chasselas Vibert,	Stockwood Golden
	Hamburg,
Early Malinsgre,	Trentham Black,
&c., &c., &c.,	&c.,

For a full list of varieties and prices, as well as for lists and prices of Hardy Grapes, see our Catalogue No. 4. See also general Advertisement. ELLWANGER & BARRY, Rochester, March, 1863. Mount Hope Nurseries.

Concord Grape Vines.

Our stock of vines of this justly popular grape is very large and superior, which we offer at:

25 cts. each; \$2.50 per doz.; \$12.50 per 100; \$100 per 1000.

For prices of DELAWARE, and many other kinds, see our Circular which will be sent to all applicants free of charge.

J. KNOX.

Box 155, Pittsburgh, Pa.

The Adirondac Grape.

The earliest and best native Grape, ripening two weeks before the Delaware, possessing a most delicious flavor, in fact, equal to the most delicate vinery grape.

Vines sent by Express, securely packed in sealed boxes. Yearling Vines will be sent by mail to any part of the U. S. on receipt of the price of the vine, and six cents P. O. Stamps. Address JOHN V. BAILEY, March 1st, Plattsburgh, Clinton Co., N. Y.

TRUE DELAWARE GRAPE VINES, propagated from the original vine. Also Concord, Diana, Rebecca, Hartford Prolific, Creveling, Allen's and Rogers' new hybrids, and all other valuable varieties, new and old. Downing's Everbearing Mulberry, Raspberries, Strawberries, &c. Send for Descriptive Lists. GEORGE W. CAMPBELL, Delaware, Ohio.

Grapes, &c., by Mail.

Persons at a distance can have Grape Vines, Strawberries, and all small articles carefully packed and sent by Mail, by PRINCE & CO., Flushing, N. Y.

The greatest improvement in Clothes Wringers. Agents wanted in every town of the United States. Send for a Circular. HAINES & PELL, 27 Courtlandt-st., New-York.

**The NONPAREIL WASHING MACHINE**

Is the only entirely reliable machine in use. It has been before the public two years, and has not in any instance failed to give satisfaction.

It saves two-thirds the labor and time required in hand washing.

It is a squeezing machine, and will not injure the finest clothing.

A girl of fourteen years can operate it.

It will not get out of order.

It is recommended by Mr. Judd, the proprietor of this Journal.

Prices: No. 1, \$12. No. 2, \$16. No. 3, \$20.

Send for free Circular to OAKLEY & KEATING, 73 South-st., New-York.

TEETH UPON ALLEN'S SYSTEM CAN BE OBTAINED AT

22 Bond-st., New-York.

By this method the TEETH, GUMS, ROOF and RUGÆ of the MOUTH are all truthfully represented, reflecting those delicate tints, shades, and forms peculiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evinced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, which rejuvenates the waning cheek.

A descriptive pamphlet may be obtained by addressing DR. J. ALLEN & SON, as above.

GREAT DISCOVERY.

An adhesive preparation, that is insoluble in Water or Oil and that will stick Patches and Linings to Boots and Shoes sufficiently strong without stitching. It will also mend broken Furniture, Crockery, Toys, and all articles of Household use effectually.

**HILTON'S
INSOLUBLE CEMENT,**

Supplied in packages from 2 ounces to 100 pounds. It is a Liquid, and as easily applied as Common Paste. It adheres Oily Substances firmly and completely.

Can be procured at wholesale in all large cities, and at retail throughout the country.

HILTON BROTHERS, Proprietors, Providence, R. I.

"A GOOD THING.—Having occasion the other day to use a liquid Cement, we tried the article made by Hilton Brothers, Providence, and found it to work to a charm. We therefore recommend it."—Woonsocket Patriot, Feb. 6, 1863.

**THE CRAIG MICROSCOPE.**

This is the best and cheapest microscope in the world for general use. It has just received the First Premium—Silver Medal—at the Ohio State Agricultural Fair. It requires no focal adjustment, magnifies about 100 diameters, or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of \$2.25, or with six beautiful mounted objects for Three Dollars. Address HENRY CRAIG, 182 Centre-st., New-York.

MR. HENRY CRAIG—Dear Sir: I have received the Microscope you forwarded to me, and am well pleased with it. It is a valuable instrument, one that should be in the house of every family, where they can appreciate its value. The study of nature is one that is interesting and useful. Being in company with some of my friends the next day after I received my Microscope, I was compelled to part with it.

Please find inclosed \$2.25 for another of your Microscopes. Direct to Henry V. Space, White House, P. O., Hunterdon Co., New-Jersey.

STAMMERING.

Cured by Bates' Patent Scientific Appliances, the only known means for the rapid and permanent cure of stammering, stuttering, &c.

They took the PRIZE MEDAL at the last London Exhibition, and of which the Illustrated London News, 2d Aug., 1862 says, "Mr. Bates, of Philadelphia, shows some small and ingenious instruments for the treatment of stammering, the effect of which on an individual so afflicted, is really remarkable."

For pamphlets and circulars, addressing H. C. L. MEARS, 277 W. 23d Street, New-York, P. O. Box 5066.

Acknowledged to be Superior to all Others.

495 BROADWAY, NEW-YORK.

equaled Lever, and Endless Chain Horse Powers, Threshers
and Cleaners, Clover Hullers, Wood Saws, &c., manufactured
by the subscribers. Address
G. Westinghouse & Co., Schenectady, N. Y.

ALLEN'S PATENT CYLINDER PLOW.

This Plow derives its name from the form of the mold board, which is a segment of a perfect cylinder, with its ends cut in the style of ordinary mold boards. Its lines are thus always horizontal to the surface of the land, and consequently turn the furrow slice with the same uniformity as a wheel on its axle, and with the least possible friction. The friction is still further reduced, by the peculiar arrangement of the POINTS or SHARES, and LAND SIDE, which, combined with its other improvements, reduces the draft from ONE-FOURTH to ONE-THIRD LESS than that required by the best class of plows now in general use. For lightness of draft, simplicity of construction, ease of holding, and certainty of turning all soils of any required depth and width, it far surpasses any other plow.

Price of No. 0, is \$7.00; No. 1, is \$9.00; No. 2, is \$10; No. 3 is \$12; with one extra polished share for each plow. Price, extra, of Skim or Front Plow, \$1.50; Wrought Side Coulter and Clamp, \$1.25; Wheel, \$1.00.

All the above Plows are polished, strong, and highly finished, and are warranted to give entire satisfaction when properly managed. Polished Steel Plows can be furnished of each of the above sizes.

Also every style of the latest improved PLOWS, HARROWS, CULTIVATORS, and a full assortment of AGRICULTURAL and HORTICULTURAL IMPLEMENTS; FIELD and GARDEN SEEDS; PERUVIAN and MANIPULATED GUANO; SUPERPHOSPHATE, guaranteed to be the best in the market, and perfectly reliable; Poudrette; Plaster of Paris, &c.

R. H. ALLEN & CO.,

SUCCESSORS TO R. L. ALLEN, 189 & 191 WATER ST., NEW-YORK.

BAKER'S PATENT DOUBLE PLOWING MACHINE.

CHICHESTER'S COMBINED FURROWING, COVERING, CULTIVATING, HOING, HILLING, and POTATO DIGGING MACHINE. Manufactured and sold by GRIFFING, BROTHER & CO., 60 Courtland-st., New-York.

THE "EXCELSIOR BURR STONE MILLS,"

AND

ANTI-FRICTION

HORSE POWERS,

Have taken the HIGHEST PREMIUMS WHEREVER EXHIBITED! NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS in 1861.

THE MILL may be driven by horse, water, or steam power, does its work equally as well as the best flat stone mills in milling establishments, and requires but *one-half the power* to do the same amount of work. They are made in the best manner, and will last *thirty years*, and cost *nothing for repairs*.

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT. more work than ANY OTHER POWER IN USE.

EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

Liberal discount to dealers—Agents wanted. State, County, and Shop Rights for sale.

For Circulars and further information address

E. H. BENNET, Late Bennet Brothers,
42 and 44 Greene-st., New-York.

MILL STONE DRESSING DIAMONDS, Set in Patent Protector and Guide.

For sale by JOHN DICKINSON,
Patentee and Sole Manufacturer, 64 Nassau-st., New-York.
ALSO Manufacturer of GLAZIER'S DIAMONDS.

Miller's Patent Hay Press.

Worked by one horse will bale one ton of hay per hour, not exceeding in cost 50 cents per ton. Can be worked in any ordinary barn. Also Portable Press, worked by two men, will bale hay for \$1 per ton, and has more than double the power of any other portable press in use. Also Miller's ROCK AND STUMP EXTRACTOR, is superior to any in use.

The Cranberry and its Culture.

The Subscriber has issued a circular from the press, treating on the Cranberry and its Culture. Said Circular will give persons the proper information as to the commencement of the culture. He will take pleasure in forwarding them to all parts of the United States, to those sending stamp to pay postage. Persons wishing plants in large or small quantities, may receive them by express, for wet or dry soil.

Address: GEORGE A. BATES, Bellingham, Norfolk Co., Mass.

BASS BARK OR MATTING—FOR BUDDING and Tying Purposes. Price 20 cts. per pound, \$18 per 100 pounds. For sale by SHEPPARD & SEWARD, 214 Pearl-st., New-York.

RUSSIA OR BASS MATS, SELECTED EXPRESSLY for budding and tying, GUNNY BAGS, TWINES, HAY ROPES, &c., suitable for Nursery purposes, for sale in lots to suit, by D. W. MANWALING, Importer, 218 Front-st., New-York.

TO FARMERS AND OTHERS.

We are manufacturing a Genuine Article of FINE, MEDICINE, and COARSE BONE DUST, or RAW BONE SUPERPHOSPHATE OF LIME, manufactured from unburned Bones, containing all the Animal and Chemical Fertilizing Properties. Please address the Manufacturers, and get the Intrinsic Value of your money.

N. B. A Liberal Discount made to Dealers for Cash, Address: A. LISTER & BRO., Tarrytown, Westchester Co., N. Y., Or Newark, N. J.

PURE GROUND BONE.

Farmers and Dealers will do well to send in their orders for BONE early, as the demand is heavy. We will give you a PURE ARTICLE. North River Agricultural Warehouse, GRIFFING, BROTHER & CO., 60 Courtlandt-st., New-York.

GUANO.

CALIFORNIA AND PATOS ISLAND GUANO, rich in ammonia and phosphates, of which we are sole importers; also the celebrated ICHABOE. All for sale in lots to suit purchasers. Apply to WAKEMAN, DIMON & CO., 73 South-st., New-York.

Fish Manure.

Believed to be the best and cheapest manure in the market. As it can not be kept in store, and a considerable quantity has to be brought from the factory at a time, I will receive orders deliverable ahead. Price \$25 per ton, 2000 lbs., packed in barrels. Order soon.—Bone-Dust, Superphosphate, Guano, Plaster, &c. JOHN VANDERBILT, 23 Fulton-st., New-York.

POUDRETTE.

Farmers and Dealers supplied with a pure article. Send for Farmers' Agricultural Almanac for the year 1863. GRIFFING, BROTHER & CO., 60 Courtlandt-st., New-York.

BAUGH'S RAW BONE SUPERPHOSPHATE OF LIME.

BAUGH & SONS, MANUFACTURERS AND PROPRIETORS, No. 20 South Delaware Avenue, PHILADELPHIA.

This Manure is manufactured from pure Raw Bones, and warranted to contain all their original organic matter—no burned or calcined bones are used, and it is sold under a guarantee from the manufacturers that it is free from adulteration.

Last season the demand for this manure exceeded that of any former one, and with few exceptions the results have been highly favorable. No pains will be spared to maintain its standard of popularity. SEND IN YOUR ORDERS EARLY.

Price, \$16 per 2,000 lbs., Cash.

RHODES SUPER-PHOSPHATE, THE STANDARD MANURE.

Prepared from Bones treated with Sulphuric Acid, uniform in quality and regular in price.

OATS, CORN, TOBACCO, AND ROOT CULTURE, ALSO TOP-DRESSING ON THE GROWING WHEAT. "RHODES"—the long established MANURE in the American market, besides having European reputation, can not be excelled for the above seasonable crops.

Our usual large stock now ready for delivery. Dealers and farmers apply to HENRY E. MORING, General Agent, 97 Pearl-st., near Hanover Square, New-York. Or B. M. RHODES & CO., 82 South-st., Bowly's Wharf, Baltimore, Md.

COE'S SUPERPHOSPHATE OF LIME. Pure Bone Dust.

The exorbitant price of Peruvian Guano, makes these the cheapest and best fertilizers which the farmers can use. OTHER FERTILIZERS OF ALL KINDS.

R. H. ALLEN & CO., New-York Agricultural Warehouse and Seed Store, 189 & 191 Water-st., New-York.

HOYT'S AMMONIATED BONE SUPERPHOSPHATE OF LIME. A Substitute for Peruvian Guano. Sold at wholesale and retail by GRIFFING, BROTHER & CO., 60 Courtlandt-st., New-York.

100,000 BARRELS

OF THE

LODI MANUFACTURING COMPANY'S

POUDRETTE,

FOR SALE BY

JAMES T. FOSTER,

66 COURTLANDT-ST.,

NEW-YORK.

In lots to suit purchasers. This Company have the largest capital and factory of the kind in the world, and possess the best facilities for manufacturing the night soil of New-York City, for which they have the exclusive contract, into a dry, inodorous, but powerful manure—superior to any other fertilizer in market, taking cost and YIELD into consideration. Price \$1.60 per barrel, free from cartage, for any quantity over 7 barrels—or only \$16 per ton.

Beware of spurious imitations, put up in barrels to resemble this Company's brand.

Attention is called to the following letter from a farmer:

FARMINGTON, N. H., October 2, 1862.

JAMES R. DEY, Esq., President Lodi Manufacturing Co.

For several years past I have used as a fertilizer, the Lodi Manufacturing Co.'s Poudrette. I commenced in 1859. I then had a tenant carrying on my farm upon shares. He agreed to use such artificial means as I should furnish free of expense to him, but he had but little faith in anything but barn-yard manure. I purchased some Poudrette. He took it from the freight-house; opened it; came to me with eyes wide open, and said, "YOU HAVE GOT CHEATED, THIS STUFF IS NOTHING BUT DIRT." I told him, "I supposed I had; it was nothing new. I was half the fool of some who cheated, but as it cost him nothing, I wanted him to use it."

We had a piece of poor, sandy loam land, which he planted with potatoes, without manure. He put Poudrette in the hills eight rows, then omitted eight rows, and then put lime in the hill, as he had a mind to try that.

The result was, that where the Poudrette was put, the potatoes came up three or four days before the others. The tops were twice the size during the season, and at harvesting we measured two lots of each, one of which the Poudrette gave twice the quantity of potatoes, and the other in the proportion of five to three.

The lime had no perceptible effect.

We had a piece of corn land, sandy loam, (my tillage land is sandy and gravelly loam,) the corn had a liberal dressing, say ten cords of barn dung to the acre, spread upon grass land, a part ploughed in the fall before, the balance in the spring. The tenant prepared a compost to put in the hill, a mixture of night soil, hog manure and loam well mixed, several times shovelled over, and well incorporated together. This was put in the hill. In eight rows through the middle of the piece, this was omitted and Poudrette was substituted instead. The result was, the Poudrette brought the corn up sooner, of a better color, and at the end of two weeks after it came up, nearly twice as large, and it maintained it a head and shoulder above the other during the season. At harvesting, we measured the corn, and where we got five bushels with the compost, we had six bushels with the Poudrette.

This satisfied me, and convinced my unbelieving tenant that it was something besides dirt. I have used it with whatever I plant ever since, and shall continue to do so, as long as it maintains its character, and is furnished at reasonable prices. We sometimes think we save an entire crop of corn by the use of Poudrette, in case of early frost, as it brings the crop to maturity at least a week earlier.

There has been an increasing demand here since it has been introduced, and from my own observation, and the information of others, I think it does as well on upland soils, as upon sandy loam. I have not been so particular since my first experiment, but every year I left a few rows so as to be sure that it maintains its character. The present year there is a very marked difference in the appearance of a few rows left without the Poudrette, in a piece of corn not yet harvested. The appearance of your Poudrette to one accustomed to this, is not very flattering. I will relate an anecdote on this point. In 1860 I prevailed upon a neighbor to try a couple of barrels, for which I think he paid me \$4.30. He informed me afterwards that he took it into his field all alone, and opened it; said he, I said to myself, if some one will come along and give me a dollar, he shall have both barrels. No one coming along, he tried it, and has used it every season since, and thinks very highly of its fertilizing qualities. Some of my neighbors have said to me, that they thought it had been worth to them \$5 per barrel. I have used other fertilizers, such as Guano, Superphosphate, &c., most of which are beneficial, but none come fairly up to the Poudrette. One particular advantage Poudrette has over other fertilizers is, that the smell is not offensive, and it will not kill the seed.

And again, it is not so expensive. My method is, to put it in the hill with the seed. A quart by measure is ample for ten hills, at which rate a barrel will manure a thousand hills. I have known it to do well where a less quantity was used. I think nothing else should be put with it. It is a light matter to put it in the hill with the hand, as a person can drop it faster than a boy can drop corn. And it does not require the large hole necessary to put in dung or compost, and is a protection against the wire worm.

Respectfully yours,

GEORGE L. WHITEHOUSE.

The Company's pamphlet, containing directions for use and other valuable information, will be sent free to any one applying for the same. Address

Books Not Advanced.—By reference to the list on page 127, it will be seen that the prices remain the same for April as for March, with two or three exceptions. Several are struck out because no longer issued, and some additions are made. This list is good only for the month in which it appears, as during the scarcity of paper publishers are continually advancing prices, and suspending publication of many books.

The following Premiums will be continued through the month of April. See N. B. below, and page 104.

GOOD GRAPES FOR EVERYBODY.

Here is a Special Offer that will interest a very large number of our readers.

During the past year we have had grown and selected a choice stock of vines of the best two grapes for general culture now known, viz.: the *Delaware* and *Concord*.—Our successful experience in sending out 40,000 Strawberry plants by mail, all over the country, and without a dozen cases of failure, has demonstrated that with the same care in putting up and mailing, we can send grape vines in the same manner. We therefore offer to send these vines as premiums to all who will forward subscribers to the *American Agriculturist*. (See conditions below.) We believe almost every one can find two or more neighbors or others, who will subscribe for the paper if its merits and cheapness are properly brought to their notice by some one who has read the paper and can speak from experience of its value. It is now the *cheapest* journal in the country—with its many carefully prepared articles for the Farm, Garden, Household, and the Young People. Though constantly making improvements—and though printing paper and other expenses are nearly doubled—we keep it at the old price of \$1 a year. (The purchase of a large stock of paper in advance, and the great increase in subscriptions enable us to do this.) The vines we offer, are not only good ones, but they are of the best two sorts for general culture, viz.: the

Delaware and Concord.

The *Delaware* is universally conceded to be the best flavored grape, and taking into account all its good qualities, it is placed highest on the list in many parts of the country. The scarcity and high price of the vines have hitherto prevented their general diffusion, (Less than three years ago we paid \$3 each for our first stock of vines, and very small ones at that.)

The *Concord* is a very early grape, adapting it to cultivation much further north than the *Isabella* and most others. It is exceedingly productive and vigorous, and thrives even under neglect. It has been thoroughly tested, East and West, and though some think it not equal in flavor to the *Delaware*, it is pronounced *very good* by all. For general, *careless* culture, under all circumstances, we place the *Concord* first on the list. Most others put the *Delaware* far before it. (See report of the Fruit Growers' Meeting, on pages 82-3 last month.)

Our advice therefore is, that all who can do so, should get one or more vines of each variety, and afterward multiply the kind that proves by experience to be best suited to their individual locations, soils and preferences. We offer to send these Grape Vines on the following

CONDITIONS:—On and after March 1st, (not before), to those sending Subscribers to the American Agriculturist for Volume XXII. (1863) at One Dollar each, we will forward, securely packed and post-paid:

For **Two** Subscribers at \$1 each, **1** Vine.
For **Five** Subscribers at \$1 each, **3** Vines.
For **Eight** Subscribers at \$1 each, **5** Vines.
For **Ten** Subscribers at \$1 each, **10** Vines.

And for over ten subscribers, one vine for each name. We specially request that the names of any club for the vines be all sent at the same time.

Those sending for premium vines can make their own choice: if for one vine, which kind; if for two or more, what number of each, and give in full the Post Office address to which they are to be sent.

N. B.—1. The above premiums are only for subscribers sent in on or after March 1st, and will only continue open so long as our supply lasts. Probably however the supply will hold out through the month of April, and perhaps as long into May as it will do to mail the vines.

2. These premiums are special; no other premiums of any kind will be paid on names sent for these vines.

3. The mailing of the vines will commence March 27th, and continue until May 1st, or later, according to the locality to which they are sent. To all who apply early enough, a Circular Letter will be sent out about a week in advance, stating the time the plants will be mailed to them. The Circular will also give directions for the treatment of the vines, with hints on culture, etc. The plants going furthest South, will of course be sent first, and those furthest North the latest; but every application will be entered in order, as soon as it comes to hand, so that no one will be unsupplied, who applies before the entire stock of vines is exhausted.

It will of course be a pleasure, as well as for our interest in the future, to have every vine a *good* one, put up carefully and in the best manner, and to have it receive such care and attention as to make it give entire satisfaction. As stated above, we have within a year past mailed 40,000 strawberry plants, and have not heard of half a dozen cases of failure or dissatisfaction. We hope for equally good success with the Grape Vines.

Special to Subscribers in Canada, and on the Pacific Coast.—There will be considerable risk in sending vines to the Pacific Coast after April 1st. The practice of some of the Postmasters in the Canadas and other British Provinces, of charging 20 cents an ounce, after the United States postage is prepaid, will prohibit sending these vines there, except when they can be sent to a United States Post-Office near the Line, or be sent by express. When eight or more are sent together, they can frequently go by express. We do not advise planting the *Delaware* in New-Brunswick, Nova Scotia, Lower Canada, or in Upper Canada, except south of Lake Ontario. The *Concord* will often thrive further North; and in favorable locations, the *Delaware* also.

Supplying Lost Numbers of the Agriculturist.—To several inquirers. —When we have mailed the papers carefully and correctly as we always strive to do, our legal responsibility ceases. But our custom is to send a duplicate copy where the first has been lost by mail, or has been injured by using it as a specimen in securing subscribers—not when injured by lending to those who never subscribe. When specially desired, a specimen copy is supplied for canvassing. Paper is too costly to send out specimen copies at random. With the above exceptions, 10 cents is charged for extra copies, of the current or past volumes.—We can not send numbers or volumes prior to volume 16, (1857).

Back Volumes & Numbers For Sale.

We have complete sets of Vols. 16, 17, 18, 19, 20, and 21, both unbound, and bound in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, 20, and 21, unbound.....\$1.00 each.
Volumes 16, 17, 18, 19, 20, and 21, bound.....\$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.

(They can not go unpaid.)
Volumes 16, 17, 18, 19, 20, and 21, unbound.....\$1.12 each.
Volumes 16, 17, 18, 19, 20, and 21, bound.....\$2.00 each.

BINDING.—Sets of numbers sent to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL, CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE, (For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only six cents a year, if paid in advance at the office where it is received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M.,
EDITOR AND PROPRIETOR.
Office, 41 Park Row, (Times Buildings.)

ESTABLISHED IN 1842.
Published both in English and German.

{ \$1.00 PER ANNUM, IN ADVANCE
SINGLE NUMBER, 10 CENTS.
{ For Contents, Terms, etc., see page 160.

VOLUME XXII—No. 5.

NEW-YORK, MAY, 1863.

NEW SERIES—No. 196.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

'The meanest herb we trample in the field,
Or in the garden nurture, when its leaf
In Autumn dies, forebodes another Spring,
And from short slumber wakes to life again.
Man wakes no more! Man, peerless, valiant, wise,
Once chilled by death, sleeps hopeless in the dust.'
* * * * *
Says the desponding lay, 'Man wakes no more'?
O blind! who read'st not in the teeming soil,
The freshening meadow, and the bursting wood,
A nobler lesson! * * * He whose providence the change
Of day and night, and seasons crowned with food,
And health and peace proclaimed, bade Nature's hand
Point to the scenes of dim futurity.
He on a world, in Gentile darkness lost,
Pitying looked down: He to bewildered man
Bade Spring, with annual admonition, hold
Her emblematic taper.....—*Gisborne's Forest Walks*.

How often does a "doubting Thomas," in these days, desire to strengthen his faith by witnessing a miracle with his own eyes. But he has only to open his eyes to see a world of miracles. The tree, lately so dormant, with its naked trunk and apparently lifeless branches, is now developing its beautiful foliage, made up of myriads of leaves, each one a new creation—a miraculous product of the limpid blood that rises from the dank soil and courses the capillary veins of the trunk. We can tell whence grow the leaves, and describe their various forms in classifying terms, but *how* does the leaf grow? Can anything short of an ever-present guiding hand marshal the elements into their proper rank and file, and allot to each one its place as a constituent of the leaf, so that each tree shall bear leaves after its kind? The tiny seed, by accident or design, is buried in the soil—a mass of sandy clay; *how* is it, that surrounded with materials so forbidding, it feeds and grows, and produces a plant so exactly like the parent one? The manner of the growth is illustrated on another page (152), but of the why and how, who can tell? How and why is it that from

similar seeds, plants so diverse in form are produced? Take the cabbage and turnip seed for example. These are almost exactly alike, yet one yields the great leaves and the central head above the surface, while the other, planted by its side and feeding upon the same materials, develops its most valuable portion below. The seeds are so much alike in form, in structure, in the enclosed germ, and in the development of the radicles and leaves, that even the experienced eye can discern no difference. Why does the after growth, from the same soil elements, differ so widely? Illustrations innumerable are ever to be observed by the dwellers among rural scenes. Is there not enough in the diverse forms and growth of vegetable life, to constantly fill with pleasure the mind of every tiller of the soil, as he labors amid ten thousand operations of nature, that are miracles in themselves. And witnessing so constantly the actual works of an omnipotent superintending skill, should not he live carefully, standing as he does in the very presence of the Creator?—These are wayside thoughts not to be forgotten as we go forth to the labors of the field. Let us turn to the consideration of some of the practical details that must occupy the hands as well as the mind. The present season is an extraordinary one. We write in the middle of April at a time when plowing and sowing are usually in active operation. But an instalment of Winter due in February, is being paid at this late date. Much of the work of April will be crowded into May. The cold weather is likely to restrain the development of the fruit buds so much, that with fair skies and the absence of untimely frosts in May, we shall have another bountiful fruit crop. But for putting in field and garden crops the time will, at best, be so short that every possible effort should be made by good planning, by procuring help and the best implements, and by having the seed all ready, to hasten work. The absence of a great number of cultivators in the army, the wastes of war, and the abundance of currency, bid fair to create an active market, and high prices for all the farm produce that can be secured this year. Let every acre possible be put to service in the production of food or clothing materials for man, and food for beast.

Work for the Farm, Household, etc.

There is little need to indicate how time may be employed on the farm the present month. The fields invite the plow, and signs of hope are written in bud and blossom over all the plains and valleys. Renewed life makes the air vocal with song, stirs the quickened bosom of the earth, and inspires man to cheerful activity. The cultivator, above all others, should exult in his labors. The elements are his willing servants; the earth is his laboratory—the air, the clouds, and the sun, his assistant chemists. He has but to direct their labors to supply his

wants and gratify his desires. But he must accord to natural laws if he would reap benefit from them; ignorance or unskilfulness have no immunity from the penalties of their violation or neglect. Herein in great measure lies the secret of success or want of it. The observant and thoughtful learn to work *with* Nature; the uninformed and heedless often strive *against* her, and always with discomfiture.

It is then wise to seek information from all promising sources, and it is our endeavor to collect it from every possible field, and to impart it for the general benefit. The suggestions which follow are intended to indicate subjects for attention, and also in some degree to give practical details drawn from reliable sources.

Barometer.—A good instrument will give indications enabling the cultivator to lay out work with some regard to the coming weather—often an important consideration, when preparing to sow, plant, or harvest. Its cost has often been saved by this means in a single week.

Beans are in great demand at a high price for army use, and paying returns may be expected from a good crop the present season. They make but slight draft upon the soil, and are therefore well adapted for lands not fertile enough for corn. Heavy manuring increases the yield of vine without materially adding to the crop. Land in good but not very high condition is most favorable. They may be planted in orchards where tillage is needed. The white bush variety is a favorite. Plant in 2½ feet drills, 5 to 10 inches apart, according to variety.

Beef and Pork in the cellar should be examined occasionally as warm weather approaches. If needed, add salt, or make new brine and repack. The old brine is valuable to dress asparagus beds, or in the manure heap.

Bees, if properly managed, pay better on the capital invested than any stock on the farm. See directions for the month under "Apiary."

Birds.—Encourage their visits, and allow no loafing gunners to harm them. They are the most efficient checks to the increase of insects.

Books are most interesting and best remembered when immediately applicable to some work in hand. The library should be consulted day by day with reference to the various operations in progress, to gain new ideas and suggestions to improvement. For a good selection of works see our book list, on page 159.

Boys are usually ambitious to do men's work. Encourage them judiciously. Skill in all hard labor is best attained in youth. Do not, however, allow them to be overtasked. It is poor economy to save paying for hired help at the expense of the health of a child, or inducing in him an aversion to home by too severe tasking. Assign to each boy a plot of ground to be worked, and the profits enjoyed by himself.

Remember the wants of the boys now, and they will not forget yours in after years.

Broom Corn.—Prepare the ground by heavy manuring and thorough pulverization. Plant at the same time as for Indian corn, in drills four feet apart, or three feet for the dwarfish varieties. Thin to about eight inches in the row, at the first hoeing, and weed thoroughly.

Buildings.—Keep in good repair and well painted. A cheap paint for rough work is made of water-lime (hydraulic cement) mixed with skimmed milk, and colored with ochre,umber, or other materials to suit the fancy.

Cabbages are a profitable field crop in the vicinity of ready markets, and also valuable for an occasional change of diet for stock in Winter. New land is best for these plants, which need deep soil and abundant manuring. We have had excellent results on sandy soil with a liberal dressing of muck and ashes. For very early, the plants should be started in a hot-bed: for medium early, sow in the open ground as soon as it is fit to work, and for the late or main crop from the first to the middle of June. As soon as the plants are well up, apply a dressing of ashes and plaster, or air-slaked lime, to prevent the attacks of the fly. The plants may be set out as soon as they are about three inches high. The smaller kinds may be 2 feet, and the larger sorts 3 or 4 feet apart, each way. In taking up the plants for transplanting, separate them all and dip the roots in a thin mud made of soil and water mixed to the consistency of cream; this will prevent the delicate fibers from drying. It is better to set out just before a rain, but if the plants are ready and no prospect of rain, make holes with a trowel, put a pint or more of water in each, and after it has soaked away put out the plant, pressing the earth well around the roots. The varieties are numerous, and new ones are originated every year. Early York, Sugar-Loaf and Ox-Heart are good early sorts. Winningstadt is good medium—in fact good at any time. If we were confined to one sort it would be the Winningstadt. Marblehead Mammoth, Stone Mason, Late Drumhead, and Bergen, are all good Winter sorts. The Red Dutch is prized for pickles, though it is apt to be small, and slow in heading. The Savoy is, though small, fine for Winter. They are almost as rich as a Cauliflower, perfectly hardy, and good keepers.

Calves.—Read directions in April Calendar. Castrate at four weeks old. Feed with sweet, fine hay when they are turned out to graze. A few oats occasionally will not hurt them.

Carrots.—Sow as early as possible, if not already done. See directions in April Calendar.

Cattle.—Feed with hay and roots until grass is abundant. Rye-bran mash is valuable for milch cows. Give a daily allowance of grain to working oxen, and card and brush them when returned from the labors of the field. Accustom them to obey the voice without constant use of the whip. Prevent young cattle from becoming unruly by keeping the fences good. Never allow cattle to jump over one or two bars in passing to or from the pasture, or they will soon learn to jump the whole fence.

Cellars.—Keep clean and well ventilated, especially if milk be kept there. A cement floor will be a great improvement. Whitewash walls.

Chimneys.—Where wood is burned, chimneys should be occasionally burned out, or otherwise cleansed to prevent danger of taking fire in windy weather. Choose a wet, still day and fire them below with a bundle of straw.

Clothing.—Study appropriateness and economy. A loose-fitting blouse or overshirt is preferable to a coat and vest, for most out-door

work. It is cheaper, allows more freedom of motion, and better preserves the under-clothing from being soiled.

Clover may still be sown; some prefer to delay it until May. Read article on page 142.

Corn.—Nothing is gained by too early planting. The soil should be dry and warm, and the weather settled before putting in the crop. Much after-culture will be saved by thorough tillage at the first. It is well to allow grass and weeds a slight start, and then destroy them by a good harrowing before marking out and planting. Either of the corn-markers described in previous numbers, this year, will save much labor on smooth land. Read article on page 140.

Cotton was profitably raised, last year, as high as latitude 39°, owing to the extraordinary price: usually other crops would pay better. Prepare a warm soil as for corn, and plant early in rows 3½ feet apart, and 16 inches distant in the row.

Cranberries may still be planted. The best location is on swampy land, near the sea-shore, where muck and sand abound. Practical directions for managing this crop were given in the *Agriculturist*, Vol. XIX, pages 115, 142, (April and May, 1860.)

Dairy.—The first essentials are good cows and rich feed. The labors of this department will be greatly lightened by a conveniently-arranged milk-room. It should be cool, well ventilated, free from dust and offensive odors, and if possible, convenient to water. A well-stored ice-house is a valuable accessory, for securing proper temperature for cream and butter. Cleanliness in every department should be the first and constant rule. Have tubs and pails for marketing neatly painted and plainly marked. Cheese-making can be profitably conducted on a large scale by a union factory to be supplied with milk from surrounding farms, the producers to share the returns.

Debts.—Avoid contracting large debts while present high prices are maintained. Improve the present favorable opportunity for reducing the amount owed. Better pay off mortgages than buy new carriages or more showy furniture. To buy for cash and sell to safe buyers on time and on interest, is the surest method of accumulating.

Drainage.—Observe where the soil remains longest unfit for cultivating on account of water, and prepare for draining when circumstances will admit. Examine outlets of underground drains, and keep them in working order. Keep sluiceways from the road open to convey their rich deposits to the fields.

Experiments.—The cultivator's own interest and that of the whole farming community will be promoted by carefully conducted experiments in the various departments of husbandry. If, for example, one thousand parties in different sections should this year endeavor to ascertain the relative merits of planting potatoes in hills or in rows, and report their success, the question might be almost infallibly settled. So of different modes of treatment of other crops, various manures, etc. Such trials need not be upon a large scale in any individual case. Experiment upon some point connected with agriculture, carefully note all the circumstances, and communicate for the benefit of the community. A strip of land through every crop left unmanured, and another doubly manured, for comparison, will often afford much information. So of other experiments in preparing seed by some special process, etc.

Fences.—Are all in order, particularly on bonndary-lines? Putting up a rail may save a lawsuit.

Flax should be sown as early this month as the weather will admit. The "Notes on Flax-Culture" in previous numbers, this year, give full practical directions. There is a fair prospect that well-cultivated crops of this staple will be remunerative.

Gates properly made and hung, are cheaper than bars, where entrances are in frequent use. See plan of a cheaply made one on page 141.

Grass-Seed may still be sown on grain-fields and

on bare spots in meadows. Rolling, and top-dressing with fine manure, will help to ensure its growth.

Health is more frequently lost by neglect and overwork than by contagious diseases. Have the meals regular and of various diet. Severe exertion after a full meal is injurious. Take plenty of time for sleep. Be punctual in all natural habits. Avoid cool drafts when heated. Have help enough to avoid overwork. Keeping a good temper and a good conscience, tends to promote health and vigor.

Hired Help.—Remember that they are men, while requiring them to be faithful. A good table, liberal noonings, and judicious commendation for work well done, will be well repaid by their increased cheerfulness and activity.

Home should be the most attractive spot on earth. Surround it with pleasant objects. Cultivate a kindly temper in the household, and allow all reasonable privileges to the younger members of the family. Mingle commendation with discipline.

Horses should be kept stabled during the working season. Feed with grain according to amount of labor performed. If lameness or other ailment occur, give rest, and proper attention. A little neglect may result in permanent unsoundness.

Lime.—A top-dressing of 20 to 50 bushels per acre, after plowing, will usually be advantageous on wet, heavy soils. Read again the chapter last month, page 107. Keep a constant supply on hand for composting with muck for the manure-heap.

Manures are best applied on corn land, or in top-dressing meadows. Their value is greatly increased by finely dividing and thoroughly mixing them with the soil. Leave none in the barn-yard, pig-sty, poultry-house, privy, nor in any place where it cannot be made useful. A handful of ashes or dissolved bones mixed with earth and slightly covered in the hill, before planting, will give the young corn a vigorous start. It should never be in immediate contact with the seed.

Markets.—Part of the advantages enjoyed by those living near cities may be secured by the institution of Market Fairs to be held monthly or oftener as may be desirable. Read article on this subject on page 106, (April *Agriculturist*.)

Meadows.—Allow no stock to graze or trample them. While waiting for plowing grounds to dry, time may be profitably employed in taking out weeds, bushes, etc., from mowing lands. A dressing of lime will aid in eradicated moss and five-finger, and give grass a vigorous start. Harrow and reseed bare spots, top-dressing with fine manure.

Millet.—If a scarcity of pasture be apprehended, sow an acre or two of millet late in the month, to be cut and fed to cattle during the Summer. The variety known as Hungarian Grass is good. The Mammoth Millet gives a larger yield.

Oats are best sown in April. For seeding down to grass they may be put in early this month, and be cut and cured as hay, if not likely to mature.

Onions.—Read article on page 142 of this number.

Pastures.—Where straw is plenty it may be turned to good account in mulching thin spots in pasture-grounds. Sheep properly managed are the best fertilizers of pastures. Attract them to unproductive knolls by scattering salt. They will leave a valuable deposit. Never allow the grass to be gnawed down more than one inch below the surface!

Pumpkins are valuable food for milch cows in Winter. Sow on rich, deeply-worked ground, in drills half an inch deep, and 2½ feet apart.

Peas.—A low-growing variety, as the Early Washington, sown with oats early this month, will make valuable feed for hogs and sheep.

Plowing sward for corn should be performed by a skillful hand. The furrow should be laid smoothly. A dressing of lime before plowing will hasten the decay of vegetable matter, and thus give ample nourishment to the early growth.

Potatoes should be put in as early as practicable. The yield will usually be better from rows than from hills. Read notes on selection for seed on page 147.

Poultry will now begin to get their own living if permitted to go at large. Continue to feed them liberally, but allow them to range if practicable. A few hens confined in coops in the garden or fruit-yard, with their chickens suffered to go in and out at pleasure, will aid in destroying insects. Where poultry must be confined, give them plenty of chopped meat, grass, and other green food. Collect eggs daily, and introduce new breeds, if desired, by exchange, or purchase of eggs.

Pumpkins.—A few seeds planted here and there in the corn-field, or elsewhere, will, in a favorable season, yield a large amount of food for stock, without much injury to the corn.

Roads.—Keep free from loose stones and other obstructions, and in general good repair. Open ditches to convey the wash to adjoining fields.

Root Crops.—Parsnips, carrots, mangel-wurzel, and sugar-beets, are of value to afford change of diet for stock in Winter. Manure ground thoroughly, till deep, and sow in drills about two feet apart. Read article on growing carrots, p. 142.

Sheep.—See Care of Sheep and Lambs, page 137.

Sorghum can be grown with profit in other localities as well as at the West, where it was a highly remunerative crop last year. It would be a good arrangement for several cultivators to unite and secure the erection of a mill to work up all the cane grown in the vicinity. Good seed is difficult to be procured. Sorghum is preferred to Imphee for Northern latitudes; the latter succeeds best at the South. Plant from May 20th to 25th, thickly in drills $3\frac{1}{2}$ feet apart, to be thinned out to 6 or 8 inches. The seed starts very slowly, and germination may be hastened by soaking. Pour boiling water upon it until it swims, stirring it to heat all equally. Allow it to remain one and a half minutes, then cool to lukewarmness by adding cold water. Plant the same day the seed is prepared. Put in the seed the same as for corn, which it resembles in its general requisites and manner of growth.

Swine.—Keep them in good condition by liberal feeding with bran, shorts, or meal mixed with sour milk, or water, and allowed to ferment. Prevent them from rooting by a ring in the nose, and give them the freedom of a pasture, but do not allow them the privilege of the highway.

Tobacco.—Read Prize Essay page 108 last month. The pamphlet published at this office is the best work on the subject ever issued. See advertisement.

Water.—Provide plenty for all stock, where they can have free access to it.

Weeds.—Take them in hand in time. Close feeding with sheep will finally eradicate daisies.

Orchard and Nursery.

The unusual backwardness of the first half of the Spring will crowd some of the work over into the beginning of May. Planting should have been finished in April, but if the trees have been properly kept back it may still be done. Trees on which the buds have swollen should be handled with great care. It sometimes happens that those sent from a distance, in very warm weather, will start while in the package, and push out shoots several inches long. Such should be cut back very severely, to induce the dormant buds on the lower part of the limbs to start. One of the English horticultural journals publishes detailed directions for killing a tree; beginning with the advice to let it lay out so as to well expose the roots to the sun and air, and then put it out without trimming off broken roots or cutting back the top. Many who plant trees with a view to make them live seem to follow very much the same plan.

Budded Stocks.—Where the buds appear to be alive, the stock worked last year may be cut back. The cut should be made a few inches above the bud, which will leave a support to which the new growth may be tied. It can be cut away afterward.

Evergreens.—This is the great month for planting these favorite trees. Nursery stock is vastly to be

preferred to trees from the woods and swamps. Be careful of the roots; if once dried the tree will not live. Have the holes well prepared beforehand, and if the soil is sandy, add peaty earth or muck. It is difficult sometimes to stake an evergreen; a few large stones laid over the roots will serve to hold it. The term evergreen is so generally confined to the Pine family that many forget that there are several desirable kinds not of this family. Among these are the Holly, Laurel, Rhododendron, etc. These are worthy of a place in every collection. The Pine family is so large that there is a range for selection. The Norway Spruce and Arbor Vitæ, from their easy culture and rapid growth, will always be popular; nothing is better for screens. Our common White Pine is a most desirable tree. The Dwarf Pine is fine for the lawn, as it retains its deep green throughout the year.

Grafting.—There is no mystery about grafting. If farmers only knew how simple an operation it is, they would not continue their orchard of natural fruit until they can afford to employ a professional grafter. Try it on one tree, and your success will probably give you confidence to operate more extensively another year. All that is needed is some cions, a strong knife, a pocket knife, a mallet or hammer, a wedge of hard wood, and some grafting clay. Full directions are given on page 82 of March *Agriculturist*, 1860. If the cions were cut early, and have been well kept, grafting may be done until the trees are in blossom.

Insects.—The eggs which have escaped destruction will soon produce broods of caterpillars. As soon as their nests appear, destroy them with a brush made for the purpose, or wipe them out by means of a cloth wound around the end of a pole, and saturated with kerosene oil. If slugs appear on pear and cherry trees, syringe with solution of whale-oil soap, or dust the trees with lime or ashes. Look out for borers.

Layering.—Last year's shoots of grapes, quinces, and many ornamental shrubs, may be laid down and covered with 3 or 4 inches of earth. They will root more readily if a sloping cut be made about half through the branch, where it is to take root.

Mulch all newly-planted trees with straw, refuse hay, leaves, chips, or other covering.

Orchards.—But little work will be required here if pruning, manuring, and other operations were attended to at the proper season. Do not crop any but a young orchard, and that only with plants the raising of which will leave the soil in better condition than before.

Pears.—These may still be set out, cutting the head well back. Allow no fruit the first season.

Quinces.—Plant out in good soil, and give the trees as much care as any other fruit trees.

Seed-beds.—Peach and other pits, and apple, pear, and other seeds to produce stocks for grafting, if not out already, should be sown at once.

Stocks and Cuttings.—Apple and pear stocks, grape, currant, and other cuttings that have been kept in the cellar, are to be planted at once.

Weeds.—Hoe out the nursery rows as soon as weeds appear, and keep all clean and in neat order.

Kitchen Garden.

At the present writing the season promises to be a late one; frosts and snows still linger—they will depart suddenly, and then the work will come with a rush. It is in late seasons that the advantage of well matured plans will be most appreciated. The work being laid out, everything will follow in proper succession. If late frosts occur, tender plants will need protection. A board turned over rows of early peas and beans as noticed on page 115, April *Agriculturist*, will be found serviceable. It will be found advantageous to prepare frames of boards about a foot square and 8 inches high, and cover the top with cheap muslin. These serve to protect hills of cucumbers, melons, etc., both from early frosts and from insects. In sowing, avoid covering the seeds too deeply. If long cold rains

come on, it will be necessary to re-sow as soon as the weather becomes favorable. In small gardens space should be economized in every possible way. See note on page 146. A succession of crops can be taken from the same soil, but in this case the ground should be kept well manured. Cabbages and Kale may be put between rows of early potatoes. Cucumbers may be grown between Lima beans. Cress, lettuce, and radishes, may be sown in every vacant spot, and carrots and beets occupy the space between rows of beans and peas.

Artichokes.—See directions for culture on p. 145.

Ashes.—A good supply of ashes should be saved for the garden. Mixed with an equal bulk of plaster, it forms the ash compost which is of great use, not only as a fertilizer, but to dust over young plants to repel insects.

Asparagus.—In most places the beds will be producing their tender shoots. Cut as soon as large enough for the table and remove all over-grown and unfit shoots. In cutting be careful not to injure the forming buds. Asparagus knives are used in England for the purpose of cutting. We have used a kind of chisel fixed to a handle like a cane. Always cut from the root and as near to it as possible. If there is a surplus to be sent to market, tie it up in neat bunches about six inches in diameter, putting two ties of bass matting, one near the butts and the other about two inches from the top. Wash in clean water before making into bunches.

Beans.—These are very easily killed by frost, and it may be necessary to repeat the early sowing. The Valentine is the earliest, but the Six-weeks is more prolific. For pole beans, put out the poles before sowing. For Lima beans see page 145.

Beets.—Those sowed last month should now be up. They may still be sown. The Bassano and Early Turnip are best for Summer use. See last month's Calendar. The winter sorts may be put in the last of the month. Deep worked soil, where there was a well manured crop last year, is best.

Borecole or Kale.—Treat precisely as cabbages.

Broccoli.—This is somewhat like cauliflower, but is much inferior to it; as it is considered a surer crop, it is cultivated by many who do not succeed with cauliflower. The same cultivation for both.

Burnet.—Much used in salads by the Europeans. See page 145 for sufficient directions.

Cabbages.—Those in hot-beds should be hardened off ready for transplanting. See full directions in Farm Calendar, which though given for field culture, are equally applicable in the garden. Sow seed in open ground for main crop of winter cabbages.

Capsicum or Peppers.—These are very slow in their early growth and need the heat of a hot-bed to give them a start. When the season is long, they may be sown in the open bed. Plant out when the weather gets settled, and give them the warmest place in the garden. Set 18 inches or 2 feet each way, and hoe frequently. The Squash Pepper is best for plain pickles; the Large Mountain for stuffing; the Cayenne for vinegar, or medicine.

Cardoon.—Sufficient directions are given on p. 145.

Carrots.—The early crop should have been put in last month, but if the weather prevented, loose no time in sowing. The seed is slow in coming, and it is a good plan to put a few radish seed with it, which will serve to mark the rows. See page 142.

Cauliflowers.—Do not let a single failure deter you from attempting to grow this choice vegetable. Get seed from reliable sources and follow the hints given on page 146. Those in hot-beds should be planted out, or if the weather is unsuitable put them in small pots, and keep in a cold frame.

Celery.—Follow directions given on page 146.

Chines.—Put out sets early. They make a nice edging to small beds.

Cold Frames.—Get the plants out as rapidly as the weather will allow. Those where plants still remain, should be uncovered every fair day.

Compost Heaps.—Begin the season with the deter-

mination to have no waste of fertilizing material. Make a compost heap in a hidden corner, but easy of access. If necessary, plant some rows of sweet corn to keep it out of sight, but do not let it get out of mind, and place here every animal and vegetable substance that will make manure. The coarse litter raked off of asparagus beds can be put here at once. All the garden refuse, weeds that have not matured their seeds, muck, ashes and an occasional load of manure should be added. By the end of the season there will be a pile of valuable compost, ready for use next Spring.

Corn.—Plant as soon as danger of frost is past. There are many farmers who rely upon field corn to supply the table. No one will do so after trying some of the improved sweet varieties. The Dwarf Sugar and Darling's Early are among the earliest sorts; the Stowell or Evergreen is fine, but longer in maturing. It should be sown as a succession to the early sorts. It is a good plan to put in seed every week or two until July. Where the garden is not sheltered from strong winds, much protection may be given to tender things by planting rows of corn so as to ward off the prevailing winds.

Cress.—Sow for succession. The insects will now be troublesome. Give ashes and plaster when up.

Cucumbers.—Those started on sods as directed last month will be ready to set out. Make the hills rich with manure, well spaded in, and cover the plants with frames made as directed above. Put the frames on towards night, and keep them on until 8 or 9 o'clock in the morning. Sow in the open ground as soon as it is warm. It is a good plan to put in some extra seeds every few days; the insects will attack the youngest plants, and any superfluous ones left uninjured may be pulled up.

Egg Plants.—These need a long season, but should not be put out until warm weather is fully established. Those in the hot-beds may be potted off and placed in a cold frame, until the weather will allow of their being put out. Give them a warm, rich spot, hoe frequently, and supply with liquid manure.

Garlic.—Plant the sets or "cloves" three or four inches distant, in rows one foot apart.

Herbs.—Under this term are included those plants which are cultivated for use as flavoring ingredients in cooking, or for medicinal purposes. Basil, Sweet Marjoram, and Summer Savory, are the most frequently cultivated annual culinary herbs. Sow the seed thinly in rows. Thyme and Sage are perennials, and may be raised from seed, by cuttings, or by the division of old plants. Caraway, Dill and Coriander are raised from seed. Balm, Wormwood and Mint are the principal medicinal herbs grown in the garden, and are readily multiplied by division.

Hot-Beds.—The plants should be set out from them as soon as practicable. Give air every day to those which remain, and on pleasant days remove the glass entirely. As soon as the beds are out of use, put the sash and frames away under cover. If the manure is not needed immediately, make it into a neat heap and put a covering of soil over it.

Insects.—The depredations of these begin as soon as vegetation commences, and they must be combated in various ways. Dusting the young plants with ashes, plaster, or air-slaked lime, helps keep them off. Use every means to promote a vigorous growth so that the plants may get, as soon as possible, large enough to withstand their attacks. Kill every caterpillar or grub that comes in your way and every moth or butterfly that you can entrap.

Kohl Rabi.—Sow and cultivate the same as cabbages. Plant at one foot apart in two foot rows.

Leeks.—Sow in rows as directed for onions, in good soil. It is better to have the rows 18 inches apart to allow room to earth up. This vegetable is not as generally cultivated as it should be. It is used in soups and stews, and its flavor is preferred by many, ourselves included, to that of the onion.

Lettuce.—Transplant and sow every two weeks to keep up the supply. See note on page 145.

Liquid Manure.—Have a tank for liquid fertilizers

if it be nothing more than an old barrel or hog-head sunk in the ground. It should be near a supply of water, and be covered to prevent evaporation and accidents. If placed where the sink water from the kitchen can be turned into it, all the better. Hen, sheep, or even barn-yard manure may be used. The liquid should not be too strong—not darker colored than weak tea. It should be applied at evening, or better just before a rain, when it may be used stronger. Wonders in the way of forwarding vegetables can be done with it.

Martynia.—This is grown for its unripe fruit which is used for pickling, and by many considered the best vegetable for that purpose. Sow in good soil three feet apart. The pods should be gathered before they lose their tenderness.

Melons.—Plant out those started on sods, and sow when the ground is warm, as directed for cucumbers. Do not attempt to grow too many kinds in a small garden, as they will mix. The Green Citron or Nutmeg when pure, will give general satisfaction. We have before spoken in praise of the White Japan, but the seed is scarce and not generally obtainable; will be plenty enough next year.

Mushroom Beds may be made for Summer use.

Mustard.—Sow by itself for salad and greens.*

Nasturtiums or Indian Cress.—These are grown in the vegetable garden for the unripe fruit, which is used as pickles, and in the flower garden as an ornament. There are dwarf and running sorts in great variety. The tall growing kinds are preferred, as they give a greater abundance of fruit. A moist place which is shaded during the heat of the day is best for them. Supply them with brush or strings.

Okra.—This is a plant not generally known, but is becoming quite common in our city markets. It belongs to the same family as the Hollyhock and the Cotton, resembling the one in its leaves, and the other in its flowers, while its fruit is quite unlike in appearance to that of either. The seed pod is the part used, it is 4 to 6 inches long and many angled or ridged. Taken while green and tender it has an abundance of mucilage, and is used in soups and stews which it thickens and enriches. Boiled and dressed with drawn butter, like asparagus, it is, to our taste, a very palatable vegetable.

Onions.—Get the seed in as soon as possible, according to directions on page 142. Top and potato onions should be set in good soil, 3 or 4 inches apart.

Parsley.—Sow at once if not already done. It is the slowest to grow of all the garden seeds and the weeds usually get the start of it. It will be well to burn over the bed to kill the weed seeds.

Parsnips.—Deep culture is needed for their full development. Get new seed, and roll or press the ground firmly after sowing—any time in the month.

Peas.—Sow the Wrinkled Marrow varieties, such as Champion of England, to succeed the early sorts. See article in April *Agriculturist*, page 115. Hoe and provide brush for those already up.

Potatoes.—Complete planting the early varieties. Hoe as soon as large enough. A handful of ashes and plaster applied to each hill, when well up, will often wonderfully improve their vigor.

Radishes.—Continue to sow for succession. If any sowing is found to be badly infested with worms, dig the crop up at once and destroy it, as it is then useless to expect radishes, and by leaving it to grow, insects will be multiplied.

Rhubarb.—Roots may still be set, if not too far advanced, as directed in last month's Calendar. Well established plants will soon afford a supply. The leaves should not be cut, but taken off with a side-wise pull, taking care not to injure the bud.

Salsify.—Full directions were given in the March *Agriculturist*, page 84. Get the seed in very early. Hoe, weed, and thin out as soon as large enough.

Seeds.—Put out roots saved for producing seeds, if not already done. Let none but the earliest and most vigorous branches grow. Do not attempt to save cabbage seed by planting out a stump. This seed is generally obtained from those who make a

business of growing it. It can be done by selecting the best specimens of well wintered cabbages, setting them out entire, and cutting away all but the main flower stalk. In this way the stock will be kept good. Do not plant varieties of the same vegetable near each other, for fear of hybridizing.

Spinach.—The wintered stock should now yield an abundant supply for the table. In cutting, leave enough for seed. This is what botanists call a *dioecious* plant, that is, it produces its barren or male flowers on different plants from those which bear the fertile flowers. They can not be told apart until they come in flower, when the barren plants are known by the greater show they make, and the abundance of pollen they produce; one of these is sufficient to fertilize a dozen of the others. Sow the spring varieties at intervals for succession, in rows a foot apart, and thin to four or five inches.

Squashes.—The early kinds started on sods should be put out as soon as the weather will allow. Treat as directed for cucumbers. Plant Hubbard, Marrow, and other late kinds as soon as the soil is warm. Put the hills 8 to 10 feet apart each way. Besides putting manure in the hills, enrich the whole ground as the vines put out clusters of roots or feeders from each joint. Keep the young plants well dusted with plaster or air slaked lime until they have made 5 or 6 leaves, to keep off the striped bug, and watch for the black squash bug, which may be found on the underside of the leaves in the morning; destroy it by hand picking.

Sweet Potatoes.—Those who cultivate only a small quantity will find it better to purchase the plants of those who make a business of raising them. See advertising column. The 15th of the month is quite early enough in the vicinity of New-York to set the plants. Directions for successful culture are given on page 114, April *Agriculturist*.

Tomatoes.—Sow in open border for late crop. Transplant from hot-bed as soon as the weather is settled. If the season is unfavorable and there is danger of the plants getting too large, pot them and keep where they can be covered at night and during cold days, until they can be turned out. Four feet each way is quite near enough. See page 114.

Turnips.—Loose no time in getting in the early sorts. Advance their growth as rapidly as possible by hoeing. Thin and weed as soon as needed. Give ashes and plaster as soon as up.

Watermelons.—These should not be planted until the ground is thoroughly warm, and June is generally preferable to May. Warm light soil, and plenty of manure are required. Put in an abundance of seed to each hill, as much of it fails to germinate.

Weeds.—Begin the fight as soon as the enemy is in sight. Hoe, pull, and otherwise destroy.

Winter Cherry.—Cultivate and treat as Tomatoes.

Fruit Garden.

After the full directions given in last month's Calendar, there is but little to be added. Plants may still be set out if they are not too far advanced.

Blackberries.—Cut back to near root, before setting.

Currants and Gooseberries.—These start very early, but may be removed even after the buds have burst. Manure established bushes.

Grape-vines may be successfully planted if they were taken up early and kept back in a cool place. In purchasing do not choose large vines. Vines two years old, with good roots, are preferable to older ones. We have seen some vines sold, this year, with large canes and small roots, and only fit for the brush-heap.

Insects.—Make war upon them from the beginning with soot, ashes, soap-suds, and hand-picking.

Raspberries.—Cut out all weak canes, and fork in a dressing of manure.

Strawberries.—Make new beds as directed on page 146. Those grown on the hilling system should have the runners picked off as fast as they appear.

After hoeing them out thoroughly, give a good mulching of cut straw to keep the fruit always clean.

Water.—If a dry spell should occur, mulch and water all recently planted trees and shrubs.

Weeds.—Hoe the surface frequently, and keep them down from the first. Let not a weed be seen.

Flower-Garden and Lawn.

If all preparatory work is not completed, it should be got out of the way as soon as possible. Sowing, planting, turning out plants from frames and green-houses, will give abundant occupation.

Annals.—Sow according to directions on p. 148.

Bedding Plants.—A selection will be found on page 147. Those remaining in the frame or green-house should be kept from making too vigorous a growth before they are turned out into the borders. The time for setting out the bedding plants must be governed by the season. Better be a little late than to run any risk.

Box Edging.—Reset, clip old edgings; fill vacancies.

Bulbs.—Many of these have passed out of flower. The garden ought to be gay now with Tulips and Hyacinths; the bloom may be much prolonged by shading with an awning during the heat of the day.

Carnations.—Plant out and sow seed. Tie the flower stalks to stakes.

Cypress Vine.—Soak the seeds before sowing. The White and Scarlet make a pretty contrast.

Dahlias may be started on a gentle hot-bed or in a cold frame. Cover the roots with rich earth. They may also be buried in a warm and sheltered border, where they may be covered at night with a mat or other protection.

Daphne Cneorum.—We have before noticed this most beautiful little evergreen shrub. It flowers freely, often blooming Spring and Fall. Plant early.

Dicentra.—For hardiness, ease of propagation, and beauty of foliage and flowers, there is no plant superior, if equal, to *Dicentra spectabilis*. It is propagated by dividing the root.

Evergreens.—Plant upon the lawn, observing the precautions mentioned under Orchard and Nursery. Dwarf sorts, especially the broad-leaved kinds, should be introduced into the borders with a view to winter effect. Rhododendrons, Laurels, Tree-Box, and some of the Dwarf Pines and Junipers, are appropriate for this purpose.

Funkia, or Day Lilies. Divide clumps and reset.

Fuschias.—Turn out after frost is over, and keep tied to stakes. They do best if partially shaded.

Geraniums.—The bedding sorts may be set out. Tom Thumb is most commonly used for this purpose, but there are many others desirable for their beauty of flowers and foliage.

Gladiolus.—Plant out the bulbs in good soil. The fine varieties are now at a moderate price, and should be in every garden.

Grass Edgings.—Set as directed last month. Keep nicely trimmed and cut.

Gravel Walks.—Keep free of weeds; roll often.

Heliotropes should not be brought out until the weather is quite warm.

Honeysuckles and other woody climbers, set early. Tie up to trellises. Layer to increase the stock.

Japan Lilies.—These are perfectly hardy. Set the bulbs early. They are worthy of a place.

Labels and Stakes.—Have a good supply of Dahlia stakes in readiness, as well as smaller ones for Carnations, etc. On sowing seeds, label each kind before putting in another. A smooth pine label smeared with a little white paint, and written on with the lead-pencil before the paint is dry, will answer best. We do not like "indelible pencils."

Lantanas.—Set in poor soil, when safe from frost. Lawns should be mowed evenly as soon as the grass is long enough to cut. Mow as needed.

Mignonette.—Sow where wanted, not transplant.

Petunias.—These popular plants may be grown as annuals, as they bloom very soon from the seed. The choicer sorts are propagated by cuttings.

Roses.—These should be in great abundance in every garden. Turn those wintered in pots into open borders. Keep the climbers neatly tied up.

Transplant from hot-beds. Tender plants may

be shaded during the heat of the day by a shingle.

Tropaeolums.—Sow in a warm place.

Tuberose.—Plant early in rich soil in a warm spot.

Verbenas.—Put in masses, securing variety in color.

Virginia Creeper.—No vine exceeds this in beauty of foliage, hardiness, and cleanliness—qualities which render it desirable for piazzas and buildings. Put out early this month.

Weeds.—Keep them out. The onion or bayonet hoe is a useful implement in flower-gardens.

Wistaria.—Set early. This beautiful most desirable climber is quite hardy around New-York.

Green and Hot-Houses and Conservatories.

During the present month all but the tropical plants are taken out of doors. The removal should be gradual, beginning with roses, verbenas, and other hardy kinds, and bringing out the others as the weather becomes settled and warm. Those which are retained in their pots should be placed where they will not be overturned by high winds, and where they will be shielded from the intense sun. An evergreen hedge or screen affords an excellent protection. In the hot-house where tropical plants are kept, much less fire heat will be needed, and the ventilators should be kept open as much as possible without unduly lowering the temperature. Although many plants will be removed, the skilful gardener will not let the house appear deserted. Those which remain should be arranged so as to make a good display, and a few free-blooming green-house plants or even annuals should be kept to relieve the barrenness.

The bedding plants, when put out, will be frequently found to be pot-bound. In order that these should have a vigorous growth it is necessary to untwist and spread the roots, and, if many of these are broken, head back the plant. When badly pot-bound plants are set out without this precaution they do not flourish, and it will be found, when taken up in the Fall, that the roots have scarcely extended beyond the original ball.

Cactuses.—Plants of this family may be propagated by cuttings, which will be less likely to damp off if allowed to dry for a few weeks.

Camellias should now be in a fine growing condition. Syringe often, and when put out of doors see that they are shaded during the heat of the day.

Cuttings of woody and succulent plants may still be made. Shade them until they have struck root.

Grapes.—As these will be in such different stages of forwardness, no definite directions can be given. Late vines just in flower should have but little syringing. Allow the bees free access to them. Keep fruiting vines well syringed, and pinch back all growing shoots that will interfere with the development of the fruit. Use sulphur for mildew.

Inarch plants that are not readily struck from cuttings, such as Camellias, Oranges, Lemons, etc.

Insects.—Do not let these be neglected in the press of other work. Entrap and kill every moth.

Platycodon.—Make cuttings of the prunings.

Water freely, as evaporation is now more rapid.

Apiary in May.

The necessity for feeding weak stocks may not be entirely past before white clover blossoms. Should unfavorable weather for the bees to work, occur during the flowering of fruit trees, but little addition can be made to the stores. A swarm may occasionally issue at such a period, from a second-rate hive which has husbanded its stores by rearing no drones. Should this occur while flowers are scarce, they will need a supply of provisions. Danger from robbing is not entirely past until plenty of work among flowers keeps the bees from mischief.

An experienced bee-keeper can tell with much certainty, by an occasional examination of the hive, when to expect a swarm. This event is not always indicated by the bees clustering thickly on the outside of the hive. They frequently do this when there is no call for activity in the fields. To examine for signs of swarms, the bees are first

quieted by blowing tobacco smoke among them, and the hive is carefully inverted. If honey is being obtained in abundance, a swarm will usually issue the first fair day after one or more queen cells are sealed over. These cells, numbering from three to twenty, are to be found on the edges of the comb. They are easily distinguished, being much larger than ordinary cells. Have stands, hives, etc., all in readiness before swarming commences. Newly-painted hives are objectionable; better leave them unpainted until later in the season, when the bees will not leave so readily. Worms will continue to be found on the floor of the hive until the bees have increased so as to occupy almost the whole space. Many can be trapped. Split sticks of elder, remove the pith, cut small notches in the sides through which the worms may enter, and lay them flat side downward on the bottom of the hive. Examine them every few days and destroy the occupants. A wren-house near the stand will aid in extirpating the millers. Boxes should not be placed on the hives while the bees are working among dandelions, if honey of a good color is desired. A yellow stain is imparted from the dandelion flowers.

Containing a great variety of items, including many good hints and suggestions which we give here in small type and condensed form, for want of space elsewhere.

Good Premiums Open.—We refer our readers to pages 160 and 155 for some premiums worth looking after. The grape premiums will close very soon.

The Calendar of Operations, or hints on work for the month, occupies considerable space at this season. The suggestions are numerous, and will doubtless afford material for thought, and hints for practice. We trust the paper would not be considered valueless, if there was nothing in it after this fifth page.

To Correspondents.—Perhaps no other apology need be given to those whose letters are yet unanswered, than to say that our letters average over 300 a day throughout the year, and that two-thirds of them arrive between Dec. 1 and May 1. The "Farm, Garden, and Household," embrace topics almost numberless—different field and garden crops, fruits and flowers, modes of tillage; domestic animals and their diseases; household labors, etc. The questions asked upon these, by a hundred thousand intelligent readers, are so numerous that we cannot promptly attend to them all, even were we able, without thought and an investigation, to respond in all cases. We have several hundred letters on hand marked "for immediate reply;" the "immediate" will be just as soon as we can. We doubt if any of our correspondents work as many hours a day (and night) as do the principal editors of the *Agriculturist*.

How to Invest Money.—Many of our readers are continually inquiring how they may invest a little surplus money. We can not answer the queries by letter, and do not like to advise others. We are not overburdened with money, but as our subscriptions are mainly received at the beginning of the year, we have to carry considerable sums to meet the expenses of the summer and autumn months, and this year we have seen nothing better than the "Five-Twenty U. S. Bonds." They pay six per cent interest per annum, in gold—the half year's interest payable on May 1st and November 1st, and are issued in sums as small as \$50. These bonds are always salable, so that one can convert them into money at any time, and they pay interest to the holder every day he has them. In time of peace, such bonds have stood as high as 20 to 25 per cent premium. (We only wish that the high price of printing paper did not prevent our carrying a good lot of them to future years.) For temporary investment, those with "interest coupons" are best; the coupons can be cut off as they become due, and be used the same as gold. For permanent investment the Registered Bonds are perhaps preferable, as they can not be lost or stolen, or destroyed by fire, when they stand in the name of the purchasers. Full particulars about these bonds, the mode of obtaining them, etc., will be found on page 156, in the advertisement of Messrs. Fisk & Hatch, who are recognized Agents of the Government, and to whom any investments can be confidently entrusted.

Warts on Horses.—John Emory, Randolph Co., Ill. The most certain cure for warts is to remove them with a sharp knife. Caustic applications may be successful, where cutting is not practicable. Nitrate of silver, (lunar caustic) is often used for the purpose. Mayhew, recommends a paste made of sulphuric acid and powdered sulphur, which can be applied by means of a flat piece of wood. Warts should be removed as soon as they make their appearance; if neglected they become unsightly, and additional ones are apt to grow.

Lice on Horses.—Elijah Bailey, Lambton Co., C. W. Sweet oil, well rubbed into the hair of the horse will destroy lice. Other oil or grease will answer, but it would not be so agreeable to the animal or his owner.

To Prevent Sows Over-laying Pigs.—This is a frequent occurrence, generally happening in small pens or where much long straw is allowed for bedding. The Ohio Farmer suggests a remedy to prevent the pigs from being crushed against the wall, viz.: to put a board in the form of a shelf around the wall, about a foot above the floor. The board may be 8 or 10 inches wide. This will leave a space underneath for the pigs, where the sow can not lie upon them.

For the Rats.—Mahlon Guenn, of Morris Co., N. J., writes to the *Agriculturist* that, after 20 years of ineffectual contest with the rats in his barn, he has finally expelled them by sprinkling fresh slaked lime around the sills, and wherever the rats will be likely to get their feet into it. They don't like it, and quit the premises. Mr. G. pronounces this a certain remedy. Several other correspondents recommend chloride of lime for the same purpose. Some say it burns their feet, and others that the rats don't like the odor of the chlorine gas.

Rats Gnawing Harness.—J. C. Marsh, Winnebago Co., Wis., inquires how to prevent rats gnawing harness after it has been oiled. Kill the rats.

A Great Egg.—I. Sues, Jefferson Co., Ky., sends a description of a mammoth egg laid by a hen 10 months old, a crossed breed of the Spanish and common dunghill. It measured nine inches in circumference one way, and seven inches the other, and weighed five and 1-16th ounces. That is large enough to crow over.

What the Dogs did in Ohio.—A. B. West, Licking Co., Ohio, sends to the *Agriculturist* an extract from the Report of the State Auditor of Ohio, by which it appears that during the last year the dogs killed 32,061 sheep, worth \$63,868.37, and also injured 24,301 sheep to the amount of \$23,224. Yet there are men opposed to dog laws!

To Expel Hornets, etc.—Thomas H. Smith, Rensselaer Co., N. Y., writes that hornets, bees, wasps, etc., may be effectually expelled from their quarters by spirits of turpentine, applied with a large syringe.

Lice on Cattle.—Ely Stone, Fairfield Co., O.—Apply grease or oil to the parts affected, rubbing it well through the hair, on to the skin. Kerosene oil will perhaps answer a good purpose, if most convenient.

Weight of Hay in a Mow.—A Pennsylvania farmer found, upon actual trial, that 450 cubic feet of hay, taken near the top of a mow, made a ton in weight. The average was about 400 cubic feet—less near the bottom of deep mows, and more at the top of the mow. This would be a ton for every foot in height of a mow 20 feet square; or 10 by 40 feet; or 15 by 26 2/3 feet.

The Corn-Marker Improved.—Several correspondents write that they use a corn-marker similar to the one described on page 41, (Feb. No.) but with the addition of another runner, so that three marks are made at each crossing of the field.

Invention of the Grain Cradle.—Joseph E. Armitage, Bucks Co., Pa., inquires, "When, where, and by whom was that useful implement, the grain cradle, invented?"

Flax Puller Wanted.—A. S. Plummer, Portage Co., O., inquires if there is any machine worked by horse power, for pulling flax. We know of none. Such a machine if simple and effective would be valuable.

Sorgho in Connecticut.—A correspondent at New-Milford, Conn., writes: "We intend this year to give sorgho a thorough trial. Two mills for the manufacture of the cane into syrup are being erected in this town; one by Mr. George McMahon, the other by

Messrs. Elijah Hall & Son. There will be at least 30 acres of cane planted in this immediate vicinity."

Sorghum Syrup can be made to equal the best article turned out at the sugar refiners. A keg sent to us by Blymer, Bates & Day, Mansfield, Ohio, made on Cook's Evaporator, without the use of chemicals or defecating substances, is very good. Good apparatus carefully used is requisite for obtaining a superior article.

Yield of Flax per Acre.—From 9 1/2 acres of the McKee farm in Washington Co., N. Y., sown with flax last year, there were obtained 391 bushels of seed, and 4,229 lbs. of lint. The seed was sold for \$2.87 1/2 c. per bushel, and the dressed flax at 25 1/2 c. per lb., making the product of an acre \$141. The cost for dressing the flax was 2 1/2 c. per lb., or \$11.13 per acre.

Large Product of Two Potatoes.—N. Varnum, Hancock Co., Me., writes: "Last Spring I planted two Garnet Chili potatoes, 4 eyes in a hill. Two hills did not come up, and two others sent up single stalks. They received ordinary cultivation; the product 85 lbs."

Winter Wheat in Iowa.—E. Kenyon, Henry Co., Iowa, writes that winter wheat has given better crops than the Spring variety, in that section, for two or three years past: it also now commands 20 to 25 cts. per bushel more in price. Spring wheat has usually been relied on, but much winter wheat was sown last Fall.

Straight Honey Combs.—M. Quimby, during a recent visit at the *Agriculturist* office, stated, that he had found a simple and costless plan for securing straight combs on the movable frames. He elevates the front or back of the hive about 20 degrees, the frames running from front to rear,—and finds the bees invariably build straight combs. In some 50 hives on which the experiment was tried, there was not a single failure.

Unnatural Grafting.—A story is going the rounds of the papers that a Mr. Smith—whether John Smith or not is not stated—has great success in raising fruit trees by grafting on maple and walnut stocks, and it is claimed that much harder trees are obtained. We shall be ready to believe this when we see it.

Whale Oil Soap Substitute.—Several subscribers living where this can not be procured, ask us what will serve as a substitute. Where whale oil can be obtained, the soap may be made in the same manner as soft soap. Probably the efficacy of this kind of soap is due in great measure to its disagreeable odor. A friend of ours, uses a compound with great success upon his peach-trees which might be tried on other plants. He mixes a strong decoction of tobacco and aloes, and dissolves soft soap in it, in no very definite proportion.

Blackberries.—Those recommended by the New-York Fruit Growers' Society were: New-Rochelle (which is sometimes called Lawton); the Dorchester; and the Cut, or Parsley Leaved. The last named is new and looks pretty, but we are not yet prepared to recommend it for producing fruit on a large scale.

Cold Grapery.—"J. J." After the vines are planted, the after care need not occupy over an hour a day. The Black Hamburg, Grizzly Frontignan, and White Sweet-Water or White Muscat of Alexandria, would give a good variety.

Grape Queries.—B. L. Maurer. New and vigorous vines can be obtained so easily from cuttings and layers that it is hardly worth while to be at the trouble of transplanting old ones. If done it should be in the Fall or early Spring. (Cannot tell aboutlands.)—Ectus. The Adirondac is not well enough known for us to decide. A. H. Sprinkle, Stark Co., O. If the old ground has been well cultivated we should prefer it to new, for planting with vines.

Grapes in Spring.—At the Fruit Growers Meeting, March 26th, some fresh, plump Isabella grapes were presented by Samuel Mitchell, of Steuben Co., N. Y. They were packed, at the time of picking, in boxes one foot square and six inches deep, three layers of bunches with sheets of newspaper laid between them. They were then put in a cool cellar and not opened until Spring, when they came out with more flavor, and greener stems than we have before seen.

Chrysanthemum—Maizena.—Lucie A. Partridge. In pronouncing the accent is on the second syllable, thus: chry-san-the-mum.—Maizena is named from Maize (Indian corn), from which it is made; it is

not materially different from corn starch, the name Maizena being a trade mark for a good quality of that article.

Gladliolus and Japan Lily.—J. S. F. The seeds of these should be sown as soon as the soil is warm, in a rather shady place. The bulbs must be taken up in Autumn when the leaves die off. They are three or four years in coming into flower.

Opium Poppy.—Robt. Bickford, Boyle Co., Ky. Early in the present century an unsuccessful attempt was made to produce opium in this country. We have heard of no successful trial. Narcotic plants are peculiarly modified by the climate in which they grow. The common hemp produces in Asia the *Hasheesh*, which is celebrated throughout the East for its intoxicating qualities, while here it yields nothing of the kind. We have not the S. C. Seed you ask for.

Worms Among the Verbenas.—Mrs. A. R. Sprout, Lycoming Co., Pa., finding that her Verbenas stopped blooming and the leaves withered, supposed that the trouble was caused by drouth. As no amount of watering restored them, she dug them up and found that "every root and fibre was a living mass of insects." By thoroughly washing the roots and replanting she succeeded in saving the choicest specimens. She has a seedling verbenas that is "delightfully fragrant," and asks if it is common for them to be so. There are several, so called, fragrant verbenas, but we have never seen one delightfully so. We should be glad of a cutting.

Roses and Euschias.—L. C. Weaver, Stearns Co., Minn. These can not be sent by mail. We do not keep plants of any kind for sale, but hand all orders which come to us to some one in the business. Our aim is to have no pecuniary interest in the sale of anything, so that we be without the slightest inducement to over-estimate the value of any article.

Why Cactus does not Flower.—"E. A. H.," Naugatuck, Ct. The reason probably is that it is too wet. The Cactus family are generally from countries where there is no rain for nine months in the year. Dry it for a few months—you need not fear hurting it—then on giving water it will probably throw out flower buds.

To Save Trouble of Subscribing Every Year.—A California subscriber writes: "It is no little trouble to send away off to the *Agriculturist* every year, the dollar subscription. We have no small bills, and if we had, it would still be a bother to send the small sum every year. Our paper is often interrupted for two or three months, as we forget to renew before the stoppage of the paper. I propose that you let a man pay \$5 at one time, and then send him the paper six years. The extra year will be partly covered by the interest, and by the saving of risk in five different remittances, as well as the labor of re-entering the names every year."—We accept the proposal of our correspondent, and extend it to any others who may prefer this course. It would doubtless be convenient to many to send in for two or three, or more years at a time, and it would save us no little labor in re-entering and posting the names every year. When three or more years are sent for, a receipt noting the full time paid for will be returned to the subscribers when requested.

Meteorological Notes from Illinois.—J. S. Rodgers, of McHenry Co., Ill., who has kept records for the Smithsonian Institute, sends us a summary of his observations for 1862, which we have not room for in full. The range of the barometer during 1862, at an altitude of 842 feet above the sea level, was from 28.46 inches to 29.66 inches. The thermometer varied from 95° to 15° below 0. Mean of 4 daily observations through the year, 45° 6. Rain fall, 38.47 inches. Snow 42.80 inches. Latest frost in Spring, on May 20th; earliest frost in Autumn, October 5th.

Agriculture of Massachusetts, by C. L. Flint; being the Tenth Report of the Secretary of the Massachusetts Board of Agriculture for 1862. A commendable feature of this report is the promptness of its appearance, which enables the farmer to profit at once by whatever valuable suggestions it contains. The more important contents are a report upon Pleuro-pneumonia—the fatal cattle disease; an interesting account of a series of experiments upon the use of manures; an article upon the insects beneficial to agriculture, and a report upon fruit culture. These, with other papers, including one giving the Secretary's observations upon European Agriculture, make up not only a useful but a really readable volume. Mr. Flint is doing good service to the cause of Agriculture in Massachusetts, and we regard this Report as another evidence of the industry and good judgment which he brings to the work of his office.

Is Old Seed Wheat Best?—To this question, asked in a previous number of the *American Agriculturist*, several correspondents have answered "Yes"; none say no. D. Steck, Lycoming Co., Pa., writes thus: "Our experience here is, that after three or four years, wheat begins to degenerate or 'run out'; or rather it becomes more susceptible to injury from insects. The smooth varieties of white wheat having failed, the bearded white chaff Mediterranean was introduced; but in a few years this became subject to the Hessian fly, or to the Midge, equally with the white, previously used; and now the indications are that the 'Lancaster' or Red Mediterranean, introduced three years ago, will suffer the same fate. But of some seed of the white Mediterranean saved the second year after its introduction, and sowed three years later, the crop was equal to the original, while new seed from that grown five years in succession was nearly all destroyed by insects. It is certain that seed wheat will keep good three years (and I know not how much longer), especially if it be kept dry, in the chaff or unthreshed, and free from the attacks of rats and mice."

Bulkeley's Seedling Potato.—Ectus. This is considered a good variety and preferred by some to the Peach-blau.

Lime—Quantity—Experiments.—J. S. Parker, York Co., Me. In the lime directions, page 107 of April *Agriculturist*, the quantities recommended referred to the bushels of *unstaked* lime, in the condition it comes or should come from the kilns to market. The quantity per acre will depend wholly upon the character and condition of the soil, as described in our article. It is well in all cases to leave a snail strip through the middle of a field without lime, and also to apply an extra amount to another strip, so as to observe the comparative results upon two or three succeeding crops. The information thus gained will be useful to the experimenter himself, and to others.

Hair as a Manure.—B. Marple, Baltimore Co., Md. We are not able to tell you the precise money value of hair as a manure. As it contains about 16 times as much nitrogen as barn yard manure, it is theoretically worth 16 times as much; we doubt not it is practically worth much more ton for ton. But hair is very slowly decomposed and its fertilizing effects will be only gradually developed. It would no doubt be a very lasting manure and could it be obtained at a reasonable price we should experiment with it, applied directly and in compost.

A Manure Bill.—A recent estimate of the amount of artificial manures annually used in England gives the following as about the figures:

Guano.....	\$14,300,000	Nitrate of Soda.....	1,000,000
Bone dust.....	1,200,000	Sul. of Ammonia.....	450,000
Bone Sphosphate.....	4,000,000	Other substances.....	250,000
Coprolite do.....	1,800,000	Total.....	\$23,000,000

This amount of twenty-three millions, be it noted, is for fertilizers the materials of which are mainly imported from abroad. The first and fifth items, amounting to over \$15,000,000, are used just as imported, without having their value increased by manufacture.—By the way, can not some statistical reader give us an approximate estimate of the amount annually paid by the farmers of Long Island, for stable manure from New-York City and Brooklyn, for ashes and lime, and for fish used as manure? It would be interesting also to know the amount used by some of the individual farmers.

Use of Liquid Manure.—R. P. Clarke, Cortland Co., N. Y. Fill the tanks with muck to absorb all the liquid, and work it over until fine, then apply to crops in the same manner as barn-yard manure.

Moss on Meadows.—Samuel McWilliams Chester Co., Pa. Apply a liberal top-dressing of lime and if the grass be very thin, go over with a heavy harrow, sow grass seed, roll it in and top dress with well rotted fine barn yard manure.

Scab in Sheep.—"Subscriber," Damascus, O. After shearing, scour the scabs off with stiff brushes and a snid made of a decoction of tobacco and soft soap, then dip the sheep in strong tobacco water with a little spirits turpentine thrown in after dipping every third or fourth sheep. Randall in his "Sheep Husbandry" says, he entirely cured a flock by this treatment.

Millet, etc., for Poultry.—W. F. Pillsbury, Merrimac Co., N. H. Fowls are fond of millet, and it is considered excellent. Buckwheat is also good.

Setting the Mole-trap.—"J. E.," and others. In the engraving given a year ago this month, (p. 141), the cross-piece, *f*, *g*, turns on a pivot in the upright; so also does the piece *c*. The heavy block, *b*, fastened to the strips, *e*, moves up and down on *a*, but is

help up by the short end of *e*. When *g*, is raised, the end of *c*, is released from the notch, and flies up; then *b*, slides off from the short chamfered end and drops down, carrying the points into the mole track. Perhaps the trap shown on page 140 of this paper may be more easily made, and be equally effective.

Starting a Peach Orchard.—Geo. T. Russell, Cheshire Co., N. H. The usual method is to plant trees one year after budding, selecting from the nursery, so as to have only known varieties. As seedlings are harder than budded trees, in colder climates pits of good sorts, from bearing trees in your vicinity, may be planted. Peaches come nearly true to the kinds planted, so it is not difficult to raise an orchard of good seedlings. In your northern latitude, 15 feet (193 to the acre) is a suitable distance for peach trees, and 30 feet (48 per acre) for apple trees, so as to prevent shading.

A Good Fruit Locality in Niagara Co., N. Y.—We remember that some 25 years ago, when peaches and other fruits were almost wholly cut off by Spring frosts, there was a belt along the southern shore of Lake Ontario, where, owing to the influence of that large body of water, the peach crop was saved and an abundant yield secured. We believe this experience was not confined to any particular year. In a recent letter to the *Agriculturist*, a subscriber gives some statistics just gathered, concerning the four Lake School Districts, in the northern part of the town of Wilson, Niagara Co., comprising a strip about 1½ miles wide, and 6 miles long: Apple trees growing, 12,434, of which not half are yet bearing; product last year 18,275 bushels.—Pear trees growing, 3,132.—Grape vines growing, 12,578, all Isabellas; product last year 57,500 pounds; wine manufactured, 1100 gallons. One vineyard of 500 Isabellas yielded last year, by actual weighing, 17,000 lbs. of grapes, of which 10,500 lbs. were sold, and 6,500 made into 631 gallons of wine. (The age of the vines is not given. Nothing is said of the peach crop.)

Prolonging the Strawberry Season.—E. Westfall, writes to the *Agriculturist* that in Autumn he covered a portion of the ground between his strawberry rows with cut straw, to keep the weeds down. This proved effectual, but the straw was put on so thickly that the plants started late, and blossomed and ripened fruit 10 days longer than those not thus treated—making a strawberry season of 3½ weeks with the same variety.

A Western Strawberry Patch.—S. S. White, Mercer Co., Ill., writes that "on moving West, I was told that Eastern agricultural papers were not suited to that climate, and that I might save the expense of the *American Agriculturist*. I took the paper, however, read it, and acting on its suggestions planted a strawberry bed 4½ rods long, by 2 rods wide, from which I picked last season, 10 bushels of berries, besides what 75 visitors picked and ate. Persons came miles to see the patch. I had to remind them of their unbelief in the *Agriculturist's* teachings, and hope their eyes are opened. I also had fine grapes from cuttings planted since I came here two years ago."

Shrubs from the Patent Office.—"S. R." The shrubs you name do not need any special culture. Myrica Gale will do best in a wet place.

Sketches of Bee-Houses, Implements, etc.—"J. F. S.," of St. Louis, and others. We are always glad to receive drawings and descriptions of novel bee-houses, implements for the farm, garden, household, etc., but can not decide whether engravings will be made and published, until we have examined them and formed an opinion of their utility. No charge is made for engravings of unpatented articles, when they are for public use, unless some individual interest is to be subserved, in which case the person to be benefited should justly bear the chief expense. Where the public interest is to be promoted, engravings and descriptions of patented articles are sometimes inserted, though in such cases it is proper that the owners of the patents, who have an individual interest in the matter, should share in the expense. We are not so benevolent as to support a paper at an expense of \$70,000 a year, and let everybody use its column as a free medium of communication with the public. But the first question in all cases, is, will the publication of this or that description benefit our readers?

Currant Wine 28 Years Old.—A bottle of currant wine, made in 1835, was recently presented at the Fruit Growers' Meeting by J. L. Gourgas, of Middlesex Co., Mass., and pronounced very good. Mr. G., stated that the currants were boiled before pressing; the expressed juice was left to ferment in the tubs, then put in wine casks, and one gallon of the best French brandy added to twenty-eight gallons of the currant juice, with sugar enough to make it palatable.

Live Forever as a Weed.—"L. D. B.," Plymouth, Conn. Some months ago we asked for information respecting this plant, and learned from one correspondent that hogs would uproot and destroy it. The Live Forever is different from the Houseleek. The latter has a dense cluster of leaves close to the ground, while the Live Forever, though of the same fleshy character, has its leaves along a stem which is a foot or more high.

The National Almanac.—In referring to this valuable work, in March, the price was wrongly given at \$1 50, which was considered cheap enough. We are glad to say the price is only \$1 25 in the better binding. We add it to our book-list on page 159.

The American Farmer and Mechanic.—Numerous correspondents are informed that we know nothing about this paper, and have seen no number of it since January. Our own legitimate business is all that we can attend to, and we can not devote time to answering inquiries about other papers, or to getting premiums from them which have been promised, and are not forthcoming.

American Bee Journal.—J. B. Cripp, Marshall Co., Iowa, and others. The above journal, formerly issued at Philadelphia, has been discontinued, for the present at least. Journals devoted to a single special department of Agriculture or horticulture, have not yet been found self-sustaining.

A Safe Promise.—An Iowa subscriber writes, "After trying a week without success, to procure subscribers for the *Agriculturist*, I told five persons I would send them the paper, and if at the end of the year they did not think it worth the money, I would make no charge. In a few days after they received their first number they were so well pleased they all paid up. If all your subscribers would try this plan, they could benefit their neighbors, and increase your circulation with very little trouble." Many others have made the same experiment, and have thus secured valuable premiums.

Cecropia Cocoon.—E. S. Holmes, Niagara Co., N. Y. Specimen received, and is doubtless the *Atacus Cecropia*. The caterpillar, when full grown, is about 3 inches long, and the moth spreads its wings nearly 5 inches. The cocoon is a silky material which perhaps might make a strong fabric, if obtainable in quantity.

Boots and Shoes.—"Homespun," advises those farmers who wish to reduce the cost of shoeing the family, to buy leather and make the boots and shoes themselves. Any one will be willing to do it after the annoyance he has had with split leather and ripped seams.

Climate at Puget Sound, W. T.—At first thought, one would hardly expect to find many readers of an agricultural paper in the newly settled regions on the Pacific Coast. But the enterprising men who go out to clear up land and build themselves homes in the Wilderness, are just the ones who are on the alert for every hint to be derived from a paper devoted to their chosen pursuit. On the morning of the 21st of every month, we make up for the mail a large edition of the *American Agriculturist*, to go out by the California steamer, to be distributed to subscribers scattered all the way from Western Mexico to Washington Territory, north of Oregon—hundreds of copies going to the latter region. A letter before us from J. H. Nagel, dated at Puget Sound, Dec. 19, (lat 42°,) describes the season up to that date as similarly mild and spring-like, to what it was on this side of the Rocky Mountains. Cattle were grazing in the fields, and potatoes and turnips were still in the ground unfrozen. Mr. N. says he has been there ten years, and that, except in 1861, he has never seen snow enough for more than one week's sleighing during a Winter. He compares the climate to that of Italy, with the heat of mid-day in Summer tempered by cooling breezes. The mild Winter comes on almost imperceptibly. We suppose this description applies only to places immediately upon the Coast, and under the influence of the Pacific Ocean, which of course, varies but little in temperature, throughout the year.

Weather Notes.—W. G. Phelps, Geauga Co., Ohio, and others. It is interesting to see and compare notes from different parts of the country, to notice the variations of temperature, beginning of storms, etc., but of course we have not room to publish many such.

Spring-Winter in New-Hampshire.—Sumner C. Hill, in a postscript to a letter dated Conway, N. H., (lat. 44°.) March 13th, 1863, says: "Thermometer 18° below zero this A. M.... Snow 3 feet deep."

Tree Cotton.—As we have before been rather severe upon a speculation of this kind, some of our old subscribers may be surprised that we publish two advertisements for Tree Cotton seed, (one last month and one now.) We have been at considerable trouble to investigate the matter before admitting the advertisements, and believe the parties are acting in good faith in introducing this variety of cotton as an experiment. We have in one case ascertained that the seed was received precisely in the way the advertiser asserted, and in the other we have seen the cotton before it was ginned. The shape of the bolls is different from ordinary cotton, and the fiber has a different feel. It is yet to be proved by experiment whether it is at all adapted to our climate, but those disposed to try it will doubtless get genuine seed offered by the advertisers.

Beware of Traveling Tree Peddlers.

—We do not like to quarrel with traveling Tree Sellers, for many of them are upright, honest men, and not a few of them are the very best agents for extending the circulation of the *Agriculturist*; but there is so much swindling by some of this class, that we must caution our readers to exercise special care in dealing with those who are far from home, and not personally known to the purchasers. The most common mode of defrauding their customers is, to get a certificate of agency from some respectable nursery, and do just business enough for that nursery to keep their agency good, and then to take orders and supply them with inferior and untrue trees, picked up here and there at nominal prices. They bluster the purchasers into paying for the trees "to get rid of them," and when after half a dozen years the trees turn out untrue, the "agent" is non-com-at-ibus. The best way is to send directly to some responsible nurseryman; or if any communication be held with the agent, listen to what he has to say, canvass his list and proposals, and when the list of trees is made out, yourself send the order direct to the proprietors of the nursery, with all specifications as to kinds and size of trees, time and mode of delivery, price, etc. If the agent be a recognized one, he will be satisfied with this course, as he will draw the same salary or commission as if he carried in the orders himself.

Grape Culture, Wines and Wine Making.

—This is the title of a work of over 400 pages, by A. Haraszthy, published by Harper & Bros. The author is a native of a wine-growing country and made a trip to Europe to collect material for this work. The European vine flourishes well in California, and what relates to the culture of the grape is of course adapted to that climate, but the very detailed accounts of the process of wine-making will be valuable everywhere.

A New Work on Vegetables.—Crosby & Nichols have just published "The Field and Garden Vegetables of America, by Fearing Burr, Jr." This is rather a descriptive catalogue than a treatise upon the culture of vegetables, and contains much information upon the origin and peculiarities of the different varieties. The author has followed the classification of Loudon, which we do not like, but this is a minor point. The work is beautifully executed, and the engravings being from original drawings by Sprague, are of course good.

Botanical Works.—A. Dumas, Ill. Gray's Manual is the best work. American Weeds and Useful Plants is fully illustrated. Both are in our Book-List.

New American Cyclopædia, Vol. 16.

—This volume completes the great work published by the Appletons. Whoever owns a set, has a valuable library. Among the striking merits of this work is the information it contains about living people, and upon peculiarly American topics. An annual volume, two of which are already issued, will record passing events.

American Pomological Society's Fruit-Lists.

—Distributed to members only. The terms are \$10 for a life, and \$2 for a biennial membership. Life members will be furnished, as far as possible, with the back volumes. Remittances for membership may be made to Thos. P. James, Esq., Treasurer, Philadelphia, or Hon. Marshall P. Wilder, President, Boston.

Catalogues.—Each year shows a great improvement in the catalogues of the various nurserymen and seedsmen. Instead of being a meagre list of articles for sale, many of them contain concise descriptions of fruits and plants, together with full directions for their planting and culture. Some of these are really valuable works of reference. We have accumulated a mass of

these, and intended to notice them in detail, but are prevented by want of space. We thank the contributors, and often in an indirect way benefit them by referring our many inquiring visitors to their pages.

Messrs. Wilder and Breck.—The proceedings at the Quarterly Meeting of the Mass. Hort. Society, April 4th, were unusually interesting. By a vote of the Society an account of the proceedings has been furnished us for publication, but we have no space left for a full report. First, an elegant Silver Pitcher or Vase, and a dozen Silver Forks, were presented as a suitable testimonial to the late retiring President of the Society, Hon. Joseph Breck (the well-known author of "Breck's Book of Flowers"). Following this was the presentation to the Society, by C. O. Whitmore Esq., of a Marble Bust of Hon. Marshall P. Wilder, who has for more than thirty years been connected with the Society—eight years as President—and labored unceasingly for the promotion of its interests, and of the horticultural and pomological interests of our country generally. The Bust was received, and resolutions unanimously passed, expressing gratitude to Mr. Whitmore, and highly complimentary to Mr. Wilder. The Bust will be placed in the Society's rooms, to which it will be a most appropriate ornament.

The Tobacco Essays—Plagiarism—New Award of the Second Prize.

The Committee to whose decision the Tobacco Essays were referred, were intelligent men, and they sought for the Essay which should give them, if they wished to engage in its cultivation, the most plain and complete practical instructions, as called for in the offer of prizes. The decision, published in the last issue of the *Agriculturist*, was made upon this ground, and in good faith, and they supposed that every essay before them came within the conditions, and was written "from practical experience or observation." After the book was stereotyped and printed, the Committee learned, to their surprise and regret, that they were imposed upon by Mr. A. B. Foster, of Crawford Co., Ill., who copied almost word for word an essay by W. W. W. Bowie, of Prince George's Co., Md., which was printed in the Agricultural Report of the Patent Office for 1849-50. This essay received a prize of \$30, which was awarded to it by a Committee of Maryland Agriculturists. While the Committee feel gratified that their decision should accord with that of these distinguished gentlemen, they exceedingly regret the unintentional injustice done to Mr. Bowie. The only amends they can make are this public acknowledgment, and to put his name to the Essay should another edition of the book be called for. The second prize of \$10 will belong to Mr. Christian Schnelder, of Madison Co., Ill. As to Mr. Foster, we leave him to reflect that he has done a very mean thing, and to the chagrin this exposure must bring him. Fortunately the discovery was made before forwarding the prize-money.

Judges for the Strawberry Exhibition.

The following gentlemen have been chosen by the Fruit Growers' Society a Committee of Judges on the forthcoming Strawberry Exhibition, announced elsewhere in this paper, viz.: Mr. Charles Downing of Newburg, N. Y.; Mr. Samuel B. Parsons of Flushing, N. Y.; Mr. Peter B. Mead, Editor of the Horticulturist, N. Y.; Prof. Geo. W. Huntsman of the Free Academy, N. Y.; Mr. Stephen D. Pardee of New-Haven, Conn.; Mr. John J. Thomas of Union Springs, N. Y., (Horticultural Editor of the Country Gentleman, Albany); and Mr. Isaac C. Winans of Newark, N. J. The first five named gentlemen have signified their acceptance; the last two have not yet been heard from, but will doubtless attend. This is a very excellent committee, all of whom are well known as practical and skillful judges of fruits, while not one of them has a special or personal interest in the propagation of any variety of strawberries. Mr. Winans was formerly largely engaged in marketing strawberries in New-York, and his practical experience will be specially valuable in this department of the exhibition.

The Michigan Agricultural College.

We are glad to learn that this, the pioneer institution of its kind in the country, is still in a flourishing condition. Like every new enterprise, it has had to contend against ignorance and prejudice. The Legislature of the State has now placed it in a condition to sustain itself until the lands granted by the General Government can be made available. The State Board of Agriculture, composed of some of the most intelligent farmers of the State, have control of its affairs. Prof. T. C. Abbot, is President of the Institution, and there is an able corps of Professors, most of whom are personally known to us.

To the farmer's son this college offers especial advantages, as he is enabled by means of his labor to defray a good share of the expenses of his education, and is brought in contact with those only who consider labor honorable. We know that the studies relating to agriculture are taught more fully than they are in most colleges and scientific schools, while the course in the ordinary and higher branches of English education is very complete. If the farmers of Michigan properly appreciated the institution it would be filled to its utmost capacity, but at present there is room for a few from other States, who are admitted at a yearly charge of \$20 for tuition, which is free to residents of the State. Catalogues and Circulars may be had by applying to Pres. T. C. Abbot, at Lansing.

Agricultural Department at Washington.

It gives us pleasure to state that there are strong indications of a desire on the part of the Commissioner and his associates to make this Department what it should be,—a real benefit to the agriculture of the country. A very capable man, Mr. Wm. Saunders, is placed in charge of the propagating garden. Prof. Townsend Glover has been selected as Entomologist to the Department—an appointment eminently fit to be made, and we are especially gratified at this, as Prof. G. was very shabbily treated by the old Agricultural Bureau of the Patent Office. We have no doubt, from Prof. Glover's ability and enthusiasm, that his labors will do much to enlighten the farmers concerning their great enemies, the insects. Another favorable indication is the determination to stop the promiscuous scattering of seeds, and to distribute them hereafter through organized agricultural societies and clubs, where they will be carefully tested, and the results made known, which is the course we have urged for a long time past. The Commissioner requests us to state that he desires all such organizations now existing, or which may be formed, to at once forward to the Department the name of its President and Secretary, in order that they may be supplied with seeds and agricultural reports. Things seem to be taking a proper shape, and we have only to ask the Commissioner that, while he is exercising proper care in the distribution of seeds, he will improve still more upon the old ways of the Patent Office, and send out such seeds, only, as are new and worthy of trial. We decidedly object to furnishing, at the expense of the people, such as are to be obtained at the seed stores. Thus, among the seeds now being sent out, several are quite common; some of them we have scattered broadcast for years past, in our free distribution.

Strawberry Exhibition.

AT THE

Office of the American Agriculturist.

The Proprietor of the *Agriculturist* invites Strawberry Growers, of this vicinity and elsewhere, to make an exhibition of their choice fruit on Thursday and Friday, June 18th and 19th,* at the American Agriculturist Office; and to give zest to the exhibition, he offers the following

PRIZES:

A—For best 25 approved varieties (one quart each).....	\$7
B—Second prize.....	5
C—Third prize.....	3
D—For best dish of market berries (two quarts of one variety.—It will be very desirable to show plants with fruit in addition).....	3
E—For second and third best do. do.	\$2, \$1
F—For largest three berries of one variety, (weight and size both being considered).....	2
G—For best New Seedling not before exhibited.....	5
H—For Second Best Seedling not before exhibited.....	2
I—For best flavored Strawberries (one quart).....	2
J—For best quart of White Strawberries.....	2
K—For best quart Everbearing.....	2
L—For best quart of Bonte St. Julien.....	1
M—For best quart of La Constante.....	1
N—For best pint of Princesse Frederick William.....	1
O—For best pint of Empress Eugenie.....	1
P—For best pint of Marguerite.....	1
Q—For best quart Fillmore.....	1
R—For best quart Cutter.....	1
S—For best quart of Triomphe de Gand.....	1
T—For best quart Wilson's Albany.....	1
U—For best quart Hooker's Seedling.....	1
V—For best quart Hovey's Seedling.....	1
W—For best quart Victoria.....	1
X—For best quart Jenny Lind.....	1
Y—For best quart Vicomtesse Hericart deThury.....	1

* No sample can compete for more than one prize.

The berries to come in competition for the premiums must be upon the tables as early as 11 A. M. on Thursday June 18th, and each specimen must be correctly labeled. The Awarding Committee will attend to their duties at 12 M.—The exhibition will not open to the public until 2 P. M. When the premiums are awarded, the names, residence, and places of business of the exhibitors will be put upon the specimens, and the prize samples designated. No Fruit exhibited will be removed before Friday evening without special permit.

* Should any peculiarity of the season require a change to be made in the date of holding the exhibition, notice will be given in the *American Agriculturist* for June,

Care of Sheep and Lambs.

Something more than high prices for wool and mutton is needed to make sheep-raising profitable. They must be well cared for, particularly at the lambing season now at hand. If the ewes have been judiciously fed, neither stinted nor pampered, the labors of the keeper will be greatly lightened. The lambs will come into the world, vigorous and active, requiring little more than the care afforded by the ewe. A few points will always need attention. Experience is the best teacher, but many have their first flock of ewes to manage this Spring, which have been bought under the stimulus of the great rise in value, and to such, the following practical suggestions will be timely. From the first, pains should be taken to render the flock tractable. A few handfuls of oats or corn scattered among them on each visit, will make the master always welcome. In this way a flock may soon learn to be led to any desired place. Pregnant ewes and their progeny are often injured by their efforts to escape when being driven to or from an enclosure. If the weather be clear and mild, it is preferable to have lambs dropped in the pasture. The field for their accommodation should be dry, and free from ditches or sunken spots, where a heavy ewe might be "cast." But during cold nights and in rainy weather, shelter is essential. A few hours exposure at such times may destroy many new born lambs. Make the shed for ewes roomy, and allow plenty of ventilation. Where the flock is large, the shed should be divided into temporary pens to accommodate not more than twenty or thirty head. In the moving about and confusion of a larger number, the young mother may be crowded away from her offspring, and the lamb be unable to suckle. Keep the pens clean, but do not use too much litter, which might entangle the new comers and prevent their rising. See that all filth is removed from about the udders of the ewes: it is also advisable to clip away any thick growth of wool which might impede the lamb in nursing. The first great point to gain is that the young should early get a good supply of food from the dam. It needs this both for nourishment, and for the medicinal effect which the first drawn milk has on the digestive organs. There should be no haste to interfere with the process of parturition. Several hours may sometimes elapse before it is completed, but unless the ewe shows signs of extreme prostration, nature will generally afford relief. If mechanical assistance be found necessary, let it be of the gentlest character, and only in conjunction with the efforts of the animal. If a ewe refuse to own her lamb, confine them together apart from the flock, and frequently give the lamb an opportunity to suckle by holding the ewe. She will usually acknowledge her parentage after a few such trials. A good ewe whose lambs have died should be furnished with one from a twin pair. She will allow its approaches more readily if the skin of her own

offspring be sewed around the body of the stranger. If no lamb be given her, the milk should be drawn from her bag once or twice at least, to prevent danger of inflammation.

Where young lambs are found astray without a natural protector in the flock, if no foster

high-bred animals. To others whose pockets admonish frugality, I would suggest the following method. Make a judicious selection of ewes from such as can be found in almost every neighborhood at moderate prices. Then procure a stout, well built, oily, and heavy fleeced Spanish buck. If the ewes are light fleeced, and have dry wool, this defect must be counterbalanced by using a buck possessing the opposite extreme. Even the first cross from a buck of this description produces an excellent sheep both for wool and the shambles. It is true, the wool will lack evenness over the body, but it will be essentially thickened, it is made to extend over the belly, the fleece is increased in weight, the sheep is rendered more compact, stocky, and nearer the ground, and the improvement is marked. The flock-master has now found the key which opens the door, and he is invited onward in the highway of future success. When ewes of this cross mature, another buck must be procured, as with intelligent flock-masters close in-and-in breeding is inadmissible. If practicable, let this second buck be the superior of his predecessor in all good points; and at the same time reject all ewes which inherit any serious defect. The flock-master must bear in mind that to grade up a flock by this method to a high standard of excellence, is a work of time; and patience must have its perfect work. But

mother can be provided, they may be given to the children to bring up as cossets. Feed them with warm fresh cow's milk. They will readily learn to drink it by giving them a quill with a strip of cloth tied around it to suck through at first. Sheep reared in this way at the house are likely to have extra care, and they usually bring an extra price in market, besides giving much pleasure to the young members of the family while rearing them. Abundant nourishment should be provided for lambs in the flock, by giving good pastures to the ewes. If grass be short, a daily small allowance of oats or corn will pay both in the lambs and the fleece. *

For the American Agriculturist.

How To Obtain a Good Stock of Sheep.

The best variety of sheep for profit will depend upon the location and circumstances of the breeder. Those contiguous to a good market will doubtless rightly prefer the Cotswold, Leicester, Downs, or some other of the mutton sheep. For those who make the fleece the primary object, my preferences are in favor of the Spanish Merino. But to obtain these of undisputed purity of blood requires an expenditure which very few are able to meet. The writer inspected a pen of bucks and one of ewes at the State Fair of Ohio, last Fall, the property of George Campbell Esq., of Vermont. His buck was held at \$3000, and the ewes at \$100 per head. These were undoubtedly pure bred Spanish sheep. Those having the means and willing to pay such prices, will save much time by commencing a flock exclusively with

good bucks must be obtained, and this will necessarily involve some expense. Fancy bucks and fancy prices are for fancy breeders and plethoric pockets; let them exclusively enjoy them. I know that good bucks can be had at from \$50 to \$100, and prices within this range should be satisfactory to both seller and buyer. But will this system of grading up a flock from mongrel ewes produce a flock of pure blooded Merino sheep? There may be incompatibility in varieties arising from physiological differences, which time and amalgamation could hardly neutralize and overcome, but in skillful hands, every succeeding cross encourages the hope that a sheep possessing all the points of a superior animal will be attained. This point I think is fully illustrated and realized by the improvements which have been accomplished in our own country, by discriminating breeders during the last 30 or 40 years. Our present American Merinos are in every respect superior animals to those imported from Spain by Col. Humphreys and Consul Jarvis, and it is equally obvious the excellences of our present improved stock are due to the Spanish blood, and we must look to this as the base or starting point of all future improvement. But in grading up a flock of sheep a few cardinal points must ever be kept in mind. 'Like begets like.' If the parents approximate perfection in any one point, the offspring will generally inherit that good point, but if the parents are both defective in the same point, the offspring is likely to be more so than either of its parents. The confluence of two muddy rivulets will vitiate still more the purity of the stream. The whole secret of grading up a

flock to a high standard of excellence is a system of counterbalancing, that is: breeding out the objectionable points of one parent by the excellences of the other, and thus stamping upon the offspring the type and characteristics we seek to obtain and perpetuate. G.

Moore's Salt Works, O., March 1863.

Kicking Cows.

"Maryland," in a note to the *American Agriculturist*, says he has always cured kicking cows, by buckling a leather strap on both hind legs, below the joint. They soon give up trying. We long since learned, by experience, that this is not so easy a matter. Unless the feet are strapped close together, the cow will slip one of them out; while if they are drawn thus together, the animal will be apt to throw herself down. If a strap is used at all, it should be a short one, and have a double buckle, so that one end can be fastened to each leg, and leave a little space between the legs. Even then a cow will generally worry and fret, and try to run, when she finds her feet entangled or confined. Kindness, and moistening the teats with milk or grease, if sore, is usually the best course. An expert milkman can usually prevent the forward movement of the leg, by grasping the teat tightly, and resting the arm against the leg. Most cows will give up kicking if the milker patiently, but firmly and in good temper, persists in simply warding their legs off with his arm. We have cured a good many kicking cows, most of them by the above treatment. Some confirmed kickers we have broken by the following method: A long narrow pen is made just wide enough at one end for the head, and spreading out at the other end to give room to her hips, and for the milker to sit conveniently by her side. A short stout leather whip (a "black snake," as it is generally called) is provided, and with this one or more heavy blows are inflicted every time a foot is raised. When the animal learns that every effort to kick is sure to bring punishment, she will usually give it up. In nine cases out of ten, cows are spoiled by bad temper and irregularity in their treatment. The cow kicks and the milker says so-o-o! This is perhaps repeated half-a-dozen times. The seventh time she chances to hit the pail or the milker, and then he scolds furiously, and probably he strikes her. The next kicks are passed over until some damage is done, when the angry scolding is repeated. We advise the use of the whip or other punishment only as a last resort; but if resorted to, let there be coolness and uniformity. If every kick brings back a blow, the cow will generally learn that much, and cease to kick.

Civilization and Animals.

Mr. Holley, of Hull Co., Nebraska Territory, writes to the *Agriculturist* that, during the first years of his residence in that Territory, he industriously killed off the wolves and foxes—in one year destroying over 170. Latterly he finds that the hares and rabbits have increased to such an extent as to prove very troublesome to his young trees—having, in the absence of their natural enemies, multiplied without hindrance. The efforts of civilization are constantly tending to destroy the natural condition of things, wherein one tribe of animals holds the other in check, so that neither predominates. By destroying the natural food of animals, they prey upon the crops. We even change the climate by

clearing away forests to make room for crops. One generation bares the earth of forests, and the next engages in planting trees.—We do not mean to recommend the preservation of wolves and foxes to keep the rabbits and hares in check, but allude to this case for the purpose of calling attention to another in which the natural balance is destroyed, to the serious injury of the farmer and gardener—viz.: the promiscuous destruction of the birds. In the older portions of the country especially, the insect-eating birds are disappearing, while the insects, their natural food, are increasing with alarming rapidity. Almost every village contains a number of over-grown boys, who, "old enough, big enough (and ought) to know better," go about with guns, and, under the pretence of hunting, shoot at everything that has feathers. We have no patience with these promiscuous bird killers, and when we see one of the lazy louts banging away at everything from a sparrow up to a robin, we think that the bird is the nobler animal of the two, for that is fulfilling the object of its creation, while the featherless biped is destroying the farmers' friends. We have laws that certain "game birds" shall be shot only at particular seasons. Why not have a law that other birds shall not be shot at all? At all events let there be such a law of public opinion, that these wanton destroyers of useful birds shall be considered in the same light with fruit thieves and other pests.

For the American Agriculturist.

Raising Turkeys—Making Grasshoppers Profitable.

Grasshoppers get their living on the farm, and for one I am not willing to board them without some return. It is my practice to send in bills against them daily (turkeys' bills), and I usually commence making them out this month. For this purpose the best two-year-old cock and two or three hens of the same age are selected. Yearling turkeys will breed, but their chicks are usually feeble, as this bird does not attain maturity until between two and three years old. Turkeys are very shy about their domestic arrangements. Their nests are usually secreted in the most out-of-the-way places, and apart from any other fowls. They should be indulged in this. I prepare nesting places for them by knocking out the heads of old barrels, and placing them in a quiet fence corner among brush or weeds. They will take to the nest quicker, if a few imitation eggs are placed there. As the eggs are laid day by day, they are removed to a cool dry place, and turned every day until the hen begins to set. The female can cover from fifteen to twenty eggs. Any surplus ones are placed under a hen at the same time, and when the brood come out they are all given to the old turkey. Persons having no old turkeys can commence by procuring eggs, and giving them entirely to a hen, but the natural mother is best. The greatest care must be taken to keep young turkeys from the wet. A single run in the grass before the dew is off in the morning may kill off a number. I make a pen about twelve feet square and eighteen inches high, to confine the young. The mother will not wander far from them. Hard boiled eggs chopped fine, and sour milk-curd are the best feed for the first week. Afterward, millet and Indian corn cracked fine are given until they are able to shift for themselves. The pen is also kept supplied with fresh cut grass, young leaves, and other green food. Loppered milk is excellent at all times,

and I think for all kinds of poultry. They love it and thrive on it. The turkeys soon learn to range for food, and no bird is more active in pursuit of grasshoppers and other insects. I think it would pay well to raise them for this purpose. To keep them from running entirely wild, and roosting away from the premises, I have roosting poles for them near the barn where they are fed every night. I have little trouble in fattening them in the Fall, as by good feeding they are kept plump all Summer, and when Thanksgiving comes and accounts are balanced, I find a large credit to their account, particularly when I reckon the large collections they have made among the grasshoppers.

Rensselaer Co., N. Y.

WALTER.

Tim Bunker on the Philosophy of Hen-Roosts.

"What upon airth d'ye 'spose is the matter with my hens?" asked Jake Frink one cold morning in March, with a face longer than usual. "Ye see, Squire, I never had such bad luck with the critters, afore, in all my life. I guess I've lost half on 'em neow sartain, and lots of what's left is limpin' around as ef they'd got some kind of disease. Shouldn't wonder if some plaguey boy had pizened the critters?"

"I guess you haven't fed 'em enough," I remarked. "Fed em!" exclaimed Jake. "Them birds have eat their weight in corn every week, I'll bet a shad, to say nothing of potatoes, beef scraps, and swill in general. You never see such eaters. They have hung around the pigs' trough all Winter, and they've pitched into the swill so ravenous, the pigs have had a poor chance; you can count every rib in their bodies. They're enough to breed a famine."

"Well, may be they have not had enough variety of food," I suggested.

"No you don't," responded Jake with emphasis. "Nothin' comes amiss to them critters. Ye see I sent and got beef seraps for 'em because they said it was cheaper than corn, and the tallest kind of fodder to make 'em lay. And I mixt up red pepper with the dough, and have fed clams, and mummy-changs, and they made no bones swallowin' of 'em, and stood with their mouths gapin' for more. I du believe they would have eaten raw alligator if I had only had it for 'em. And then they had a little of every thing that was eaten in the family, besides a cow that died winterin'. I allers have bad luck on winterin' cows. That ain't nothin' new. But my hens never died so afore, and they never had so much to eat."

"Well isn't there something wrong in the roosts?" I inquired.

"Not a bit of it. I had a grand fuss, and clearin' out last Fall, on purpose to know that every thing was right. Ye see, Polly took a notion to have the *American Agriculturist* last year, and she read about having the roosts white-washed, and clean poles for 'em to sit on, and clean floors for the manure, and I didn't hear the last on't till I had a general overhaulin'. From the day that paper come into the house, that woman was took with the hen fever, and she was dingin' at me from mornin' till night about the critters. It was, Jacob du this, and Jacob du that. I undertook to laff her out on't, but I found it was no go. I hinted to her that I didn't see much use in cleaning up the floor, when the critters were sure to nasty it agin' as soon as they got on to the roost. She said the paper insisted on clean roosts, and you would've thought she was quotin' scripture.

Says she, 'Jacob, 'spose I should say it was no use to clean up the kitchen, because you come in from the cow yard twice a day, and sometimes more, and dirty it all up! I have followed you with a broom and a mop for thirty years, and that roost is gwine to be cleaned, if I do it myself.' Well, ye see, there want no more to be said arter that. I got a lot of new poles for 'em to sit on, white-washed top and bottom, and made it look like a parlor."

"I guess your poles is the trouble," I said. "That aint possible, said Jake, for I made the poles small on purpose so they could hold on."

"There is where you made your mistake. You see the perch wants to be so large that the hen won't have to hold on. The hen is a philosopher, and knows more about taking care of herself than Jake Frink, any day. She belongs to a warm country, and her feet are the most susceptible to the cold of any part of the body, and most likely to be damaged by the frost. You will see her standing on one foot in cold weather, with the other drawn up among the feathers getting warm. After a little while, she will change position, and warm the other foot. If it were not for this process of warming, both feet would soon be frozen, and she would grow lame and die. If hens have large perches, say four or five inches in diameter, their toes are completely covered with the feathers as they roost at night, and they sleep comfortably and securely. If the perches are small, the toes are left out, and freeze in very cold weather. This makes them lame, and of course affects the general health, as a frozen limb would in larger animals. Sometimes the toe sloughs off, and if the freezing process is not repeated, the bird recovers. But if Jake Frink is the owner of the birds and does not know what the matter is, the toes are repeatedly frozen, and the hens die in a very strange and mysterious manner!"

I left Jake standing with his mouth open, as this bit of philosophy got into his head. It was so plain that he could not help seeing it. But wiser men than he are every day violating the plainest principles of common sense in their management of domestic animals. Their bodies are as much subject to law as our own, and if we do not regard these laws in providing for them, health is impaired, and oftentimes life is destroyed. There is as much philosophy in hen-roosts as there is in human dwellings, and we must know something about the habits of hens before we can suitably provide for their health.

Not long ago I was asked to come over and see Mr. Spooner, our minister. I began to think of my transgressions at once, and tried to recall what scandal I had uttered that I should be sent for. I was put at my ease when I found out that it was *my* profession and not his that was to be called into service. I may as well say that I have considerable of this work to do around Hookertown, and I don't see why it is not just as honorable to doctor hens as it is to doctor men. The only fault I have to find is, that folks don't send for me until it is entirely too late.

Mr. Spooner complained that his hens died strangely. He took the best care of them, gave them a variety of food, grain and meat, and pounded oyster shells for them, and bones; but they would droop, run at the mouth, swell in the head, and die. Some times they dropped dead from the roost. I suspected in a minute what was the matter, and led the way to the hennery, where I found a large quantity of manure sprinkled over with lime. The smell of ammonia was about as pungent as a hartshorn bottle. He had heard it said that lime was good

to cleanse roosts, and had used it without stint. In such an atmosphere, in a close warm room, the hens died of course. I ordered cleansing and a layer of dry muck to be changed once a month. Since then the minister has had plenty of eggs of his own raising. I could afford to throw in the fees, for before my visit, Mrs. Bunker's egg basket was often emptied at the parsonage, and no questions asked; since then, it has been like carrying coals to Newcastle.

Hookertown, } Yours to command,
March 20th, 1863. TIMOTHY BUNKER ESQ.

For the American Agriculturist.

Care of Fowls.

Nearly two years experience with about 34 hens, gives me, "in as great proportion," the same advantages in eggs and chickens as Mr. Thompson obtained from 75, as stated in the March *Agriculturist* (page 75). There is, however, this in my favor, that during the whole time only three of my hens died. Warmth, ventilation and cleanliness, with frequent greasing of the roosts, are pretty sure safeguards against vermin.

My poultry house is thoroughly cleaned every week, well swept, and fresh loam scattered over the floor. Sometimes, if the smell be offensive, I scatter a few handfuls of lime dust (which is always on hand) under the roosts, and sprinkle with a watering pot; this is a great purifier. [Plaster would be better.—ED.] The droppings saved during the year with the loam added will average from twelve to fifteen barrels.

A word about feeding. I am of opinion it is great economy to boil the meal. My plan is, to boil, about once a fortnight, a half bushel of cracked corn, stirring for an hour. At the same time, boil in another kettle a half bushel of small potatoes; when soft, pour off the water, mash, and mix thoroughly with the meal, then pour the whole into a tub or barrel. It keeps sweet, and cuts like cold mush. I give them plenty of this, varied now and then with a few handfuls of grain, cabbage leaves, oyster shells, and bones broken small. There has been no lack of eggs during all the Winter. W. WILSON.

Suffolk Co., N. Y.

For the American Agriculturist.

Cost of Keeping Poultry.

The appearance of my report on poultry in the March No. of the *Agriculturist*, page 75, has led to many inquiries as to cost of keeping. The answer is: one peck of corn per day, for a hundred head, in Winter; in Summer less will do. Corn being the staple food for poultry, the calculation is based on its cost. I prefer and use wheat screenings. A variety of grains is desirable; no damaged grains should be fed. The cheapest food is corn and oats ground together in equal parts. Two pounds of this stirred into one gallon of boiling water makes ten lbs. of stiff food. It may be fed warm, *not hot*.

Staten Island, N. Y.

J. C. THOMPSON.

Desirable Breeds of Fowls.

John E. Abbott, Kennebec Co., Me., writes concerning different breeds of fowls: "Common hens will yield good profit, but more can be obtained from many of the improved varieties. In deciding what breed is best, it must be taken into account whether eggs or chickens are most desired. 'Every-day layers,' as they are called, are commonly considered to be superior to others in laying qualities. A few of the best of these I will briefly describe. *Black Spanish*.

—Rather above the medium size. Their combs are single and very large. The hen's comb falls over on one side. Few fowls surpass them in the number, or size of the eggs. Their chickens are hardy. *Leghorns*.—These fowls bear a strong resemblance to the Spanish, except in color. Those who have kept them, think that they are better layers. In a report which was published in the Transactions of the Middlesex Co. (Mass.) Agricultural Society, for 1861, Mr. I. H. Felch, of Natick, stated that 'for six months, the White Leghorns averaged 95 eggs per hen; the Blue Leghorns, 80; the Brahmas, 77; and the Black Spanish, 74. These two breeds, Leghorn and Spanish, seldom set; so that it will be necessary to keep some other variety for raising chickens. *Dorkings*.—For rich, juicy flesh, the Dorkings are generally placed at the head of the list. They are not hardy, and are only fair layers. These two things will prevent their being in great request. *Brahma Pootras*.—Full grown Brahmas will weigh from 18 to 22 pounds a pair. Though not equal to the Dorkings for the table, their flesh is of excellent quality. As layers, they are highly valued. They commence laying when young—usually at the age of six months. The only fowls that come up to them in size, within my knowledge, are the Chittagongs. There appears to be but a slight difference between these and the Brahmas. Any one of these different breeds, excepting perhaps the Dorking, will almost invariably give better satisfaction than common fowls."

Bee Keeping in Minnesota.

Samuel Bates, Winona Co., Minn., sends to the *Agriculturist* a very favorable account of success in bee keeping in that locality. He selected a site with reference to the business in a valley adjoining the Mississippi River, and where plenty of basswood trees were growing on the adjacent islands in the stream. The bees find abundant pasturage, and the quality of honey is superior. Early swarms frequently make a hundred pounds per hive. Swarms coming as late as the middle of August, which would be deemed worthless at the East, will store from twenty-five to forty lbs. of honey.

Mr. Bates wintered his bees in a house, 25 feet long, 5 feet wide, 6 feet high, covered with matched boards, and well ventilated at top and bottom. It is entered by a door at the end. The hives are set in tiers one above the other on bars extending lengthwise of the house. Each hive is raised a short distance from the bottom board, to allow ventilation. As warm weather approaches and the bees become uneasy, the door of the house is opened at night and shut early in the morning, to keep them as cool as possible until a favorable day comes for setting them out. If there be snow on the ground, straw is scattered about the hives for them to alight on. Mr. B. thinks some winter shelter is indispensable to successful bee-keeping in that region, where the cold is often intense. Many have failed in the attempt to keep them the year round in the open air.

THE AGE OF HORSES can not always be known by their teeth. "Ebersol," writing from Ottawa, Ill., says he saw some neighbors at work upon an old horse, "making him over." Having cast the animal, they filed his teeth and brought them to resemble those of a young horse. He was afterward sold at a good figure in consideration of his youth! The imposition is not new! Sharpers have long practised it.

Cheap Home-Made Bag Holder.

A subscriber to the *Agriculturist* whose communication and address have been mislaid, sent a sketch and description from which the above engraving is made. It represents a cheap and apparently very convenient bag holder. To make it, take a two-inch plank block, 12x18 inches; bevel the sides half an inch, and with strong screws fasten to it two flexible uprights of half inch board, each 6 to 8 inches wide, as shown in the engraving. To use it, the top of the bag is folded over about three inches, and placed over one upright, the two are sprung together so that the fold may be placed over the other one, and it is thus held distended. The uprights are long enough to allow the bottom of the bag to rest upon the block. Where the bags are of uniform length, this will answer every purpose. We would suggest that to accommodate bags of different lengths, two short uprights might both be fastened to the block, and then two flexible strips be fixed to slide up and down in staples fastened to the outside of the stationary uprights.

Progress of Flax Cotton Manufacture.

Some progress has been made towards securing the desirable end of being able to work flax upon cotton spinning machinery, as is seen in the establishment of several factories. As yet, however, the enterprise cannot be deemed wholly successful. In consideration of the importance of this industrial interest, the Legislature of New-York, on the 22d of April, 1862, appropriated \$2000 bounty for "machinery to test the experiment of manufacturing flax cotton, to be expended under the direction of the State Agricultural Society." The Society has recently rendered a report of their proceedings in the matter. The investigation was made by a committee consisting of Hon. Ezra Cornell, Messrs. Samuel Campbell of New York mills, A. Wild and B. P. Johnson of Albany and J. S. Gould of Hudson. Only two competitors for the State bounty appeared, viz.: the Lockport, N. Y., Flax Cotton Company, and Mr. C. Beach, of Penn Yan, N. Y. After examining their processes, the committee submitted the following resolutions, which were adopted:

Resolved, That in the judgment of this Society no such advance in the perfection of machinery to test the experiment of manufacturing flax cotton has been made as to warrant the Society in awarding any portion of the sum appropriated by the Legislature, at the present time.

Resolved, That the Society will keep the execution of the trust reposed in them by the Legislature for the present in abeyance, under the hope that such valuable improvements may be effected in the coming year, as may justify the Society in awarding the whole or some portion of this amount to any such successful inventions.

Resolved, That the committee be requested to continue their investigation during the year, at such time and in such manner as may, on consultation with the President and Secretary of the Society be deemed most advisable.

Resolved, That the entire sum of two thousand dollars, appropriated by the State as aforesaid, now in the hands of the Treasurer of the Society, be deposited by him in one of the trust companies of the city of New York, where it may draw interest until it shall be required for the purpose designated by the Legislature.

Resolved, That the proceedings of the Society be presented to the Honorable Legislature."
(Signed) B. P. JOHNSON, Secretary.

The committee say in addition: "We are fully convinced that the reduction of flax fiber to flax cotton is practicable. Already great strides towards the accomplishment of this have been made, as we think, in the right direction. We feel confident that nothing is needed but intelligent and persevering efforts, to achieve a triumphant success. We deem it desirable in the highest degree that the Legislature should continue to offer a reward with a view of stimulating and encouraging the activity and ingenuity of inventors." The continued demand for cotton substitutes is inspiring inventors in every direction, and it is to be hoped that ere long their efforts will furnish us again with some material for clothing, produced at the North, less costly than cotton at 40 cents per yard.

An Effective Mole Trap.

If the moles would confine their sapping and mining operations to the fields, they might be spared in consideration of their usefulness in destroying grubs and other troublesome insects. But we have learned by costly experience that in the garden and ornamental grounds they may become an intolerable nuisance. Last year we published in the *Agriculturist*, page 141 (May No.) the best of over twenty designs for mole traps sent by different parties. A correspondent writes that upon attempting to construct a similar one, not being much of a carpenter, he found it too difficult for him. He finally contrived the simple modification shown below,

and found it to work well. His trap was sprung fourteen times, and he secured fourteen moles. In the engraving, the plank (P) 8 to 12 feet long, has a hole in the lower end which passes over a pin driven into the ground, to hold it in place. Three or more stout wires, very sharp, are inserted an inch apart on each side of the end of the plank. The pairs of wires should be about 9 inches apart. A stone or other weight, S, is added to bring it down forcibly. A common figure 4 (T) is placed under the plank, with the trigger lying across the mole track. When setting it, the track is flattened with the foot, where the trigger is to rest upon it. The plank

should have a fall of 12 to 15 inches. The mole in passing, in either direction lifts the trodden ground and the trigger resting upon it, and is instantly pierced by the descending points.

Another Improved Bow-Pin.

A subscriber to the *American Agriculturist* sends the accompanying design for a bow pin, which he considers an improvement on the one shown in Vol. XXI, page 300 (Oct. 1862.) It consists of a common wrought iron hinge, with one side fastened to the yoke, so that the other part will rest over about one third of the hole through which the bow passes. A tapering notch is cut in the side of the bow, as shown in the engraving. This arrangement allows the

bow to pass upward, lifting the loose part of the hinge; on its return, the hinge catches in the notch, and holds the bow fast. It is very convenient for yoking shy cattle, which will sometimes start while the pin is being inserted. By having the pin thus fastened to the yoke, there is no danger of its being lost, a decided advantage.

Hints on Raising Indian Corn.

In the cultivation of corn there is no stereotyped method, absolutely better than others, for every time and place. What may be best in the garden, may not be required in the field. What answers well in the small fields of New England, may not be needful in the thousand-acre lots of the West. Northern modes may not be exactly suited to the South. One can not and need not manure as highly at the West as at the East. Owing to the high price of labor at the West, one must use more horse power and less hand-labor than at the East. Yet some things are the same everywhere. Everywhere, corn is a rank feeder, and wants an abundance of food. Where the land is in a state to admit of it, the roots will run from three to five feet in quest of nourishment. Hence the need of good land and good tillage. This tillage should mostly precede the planting of the corn, for the too frequent disturbance of the ground after the roots have got established in it, breaks the surface roots, and seriously injures the plants.

As to the best manures for corn, that from the barn yard stands first. By this we mean not only the simple excrements of all kinds of stock, for these alone are not enough. The quantity may be doubled, and the quality hardly diminished, by using absorbents to soak up and save the liquid parts and the gases of the pure dung. What these absorbents are, we have often mentioned, such as muck, peat, sods, straw, tan-bark, leaves, saw-dust, etc. Yet sometimes, the dung heap and compost give out before the crops are all fed. In such cases, the farmer must use with discretion such fertilizers as gypsum, ashes, poudrette, guano, bone-dust, dissolved bones, etc. Let him be specially careful in the use of guano, hen-dung and night soil, and other concentrated manure, or he will spoil his whole crop. They need to be mixed with several times their own bulk of soil before applying them near the seeds or roots of plants.

In preparing the ground, much pains should be taken to plow well, and to mix the manure thoroughly by careful harrowing. It is surpris-

ing what a difference this makes in the rapid and healthy growth of the stalks, their exemption from the effects of drowth, and the plumpness of the ears. It saves a great deal of after-tillage, and prevents much anxiety as to the success of the crop. If the land be subsoiled, more of the roots will strike downward, and fewer will be broken and injured by the cultivator and hoe.

Corn in drills three to four feet apart, and the stalks 8 to 12 inches apart in the row, will give the best yield to the acre; but where land is cheaper than labor, it is usually more profitable to plant in hills, the rows running both ways, so that the plow or cultivator passing in both directions will do most of the work of tillage. The hill system lets warmth in on all sides, which is advantageous, especially on cold, heavy soil, or in a cool season. Corn is a sun plant and prospers best under warmth. The drill system prevents the stalks from crowding and shading each other. If planted in hills, the seed should be dropped four to six inches apart, so that the stalks and leaves will not interfere. The distance apart of hills, or drills, and of the individual stalks, depends both upon the strength and richness of the soil, and the variety in size of the corn. A good soil will support a nearer growth without depriving the roots of adequate nourishment. For the smaller varieties of corn, those growing only $4\frac{1}{2}$ to $6\frac{1}{2}$ feet high, three feet apart for rows or drills is enough. The taller, 10 feet high varieties, require $3\frac{1}{2}$ to 4 feet rows or drills. Usually $3\frac{1}{2}$ to 4 feet is preferable to 3 feet, for medium soils, and for good sized field varieties. Four stalks are as many as can grow in a hill. Three good stalks will yield more grain than five poor crowded ones.

The best varieties of corn for any locality are best learned from the general experience of a neighborhood, though it is well to try small plots of new kinds for experiment. Let it be remembered that corn is easily spoiled for seed by dampness or heating in the shock or crib. It is but little trouble to sprout a handful taken as a sample from the whole lot, by putting it in a damp soil in a warm place. No one can afford to lose the first planting, or to have a lot of deficient hills, simply for want of a few quarts of good seed. Plant corn very shallow; one inch is abundantly deep. If covered deeper than this, some of the kernels will rot before vegetating, if it chance to be cold or wet weather. Half an inch is usually deep enough. A little good, well rotted manure, or ashes, in the hill near but not in contact with the seed, helps to give the plant a vigorous start, even where the whole ground is not manured. See Calendar last month, also article on lime page 107. The latter part of May is early enough for planting at the North. Warm soil starts the plants at once into rapid and vigorous growth.

TO FASTEN A ROPE-END.—J. C. Marsh, La Fayette Co., Wis., recommends to prevent the untwisting of a rope's end, by winding it with small wire. Heat the wire to redness, then let it cool slowly, and it will bend easily. The ends can be fastened by winding them under the coil, or passing a few times through the rope.

A Farm Gate Easily Made.

The plan for a farm gate published in the *Agriculturist* page 45 (Feb. No.), has called out many designs for this desirable farm fixture. The one presented herewith, was forwarded by

a subscriber, J. T. Waters, Jefferson Co., Ill. We have added a few modifications. It is made entirely of $\frac{1}{4}$ inch boards, or 1 inch if desired to have it heavy. Two boards each 6 inches wide are used for the head-piece, *H*, one on each side of the bars *S*. The tail-piece, *T*, and middle upright, are put on similarly. The braces, *B*, *B*, 3 to 4 inches wide, will not need doubling; one piece on a side, as shown, will be sufficient.

The parts should be well secured with wrought nails, driven through and clinched. Pine or cedar boards are good; hemlock would be liable to warp; oak would be heavier than needed. A finishing cap or strip $1\frac{1}{2}$ inches wide, should be nailed along the top, to keep water from entering at the joints. The hinges are of iron, $\frac{1}{4}$ inch thick, 3 inches broad, made with an eye to receive the staple on the post, and with arms to clasp each side of the head piece. They should be bolted firmly. The latch, *L*, turns upon a pivot, and is kept in place by a small upright strip. It fastens into a notch in a strong cleat nailed upon the side of the post. Two extra hinge staples are driven into the head post, a foot or eighteen inches above the others. In Summer, the gate hangs upon the lower ones, near enough to the ground to exclude pigs and geese. In Winter it is lifted to the upper ones, to admit of swinging over snow: this sometimes saves considerable shoveling.

A comparatively light gate is preferable to a heavy one, for the reason that it is easier to handle, and it will not so soon drag the post out of perpendicular. The latter difficulty is the great obstacle to overcome. It can be in good part prevented by draining the soil about the post-hole. It is a good arrangement to pin a plank two or three feet long to the bottom of the post, extending in the direction of the gate, and fasten a short brace to this and the post, the whole to be placed under ground.

Flat Culture of Potatoes.

This can not be attained perfectly, but should be aimed at. Four to six inches is the utmost light allowable for a hill, and this should be got as early as possible in the Summer. And for this good reason: as soon as the stem is well formed, tubers are developed at the sides at a proper distance below the surface, and they will go on enlarging to their full size, if they are not disturbed. But now, if we pile up more soil around the stem, a new set of tubers will be

formed higher up than the first, which will draw away a part of the food that should have gone to the first. The consequence will be that at digging time, many of the tubers will be small, and some of them unripe. So thinks X.

Salt on Wheat.

W. H. Yale, New-Haven Co., Conn., sends to the *Agriculturist* the following account of his experiments: "In the Spring of 1851 I tried salt on wheat. The first piece, about an acre, was part of an orchard, marked off into ten pace lands. I sowed salt on alternate lands, using five bushels per acre, and harrowed it in with the wheat. On these lands, the grain ripened sooner, was larger, and free from rust. The next year the salted part yielded twice as much hay as the other portion. The second piece, of two acres, had been planted with corn the year before on the sod, and was badly infested with grubs. They had destroyed much corn, and also greatly injured the wheat. On the alternate lands, treated with salt, the wheat headed out a week earlier, and the yield was doubled. I also sowed another field of poorer soil than either of the above, using salt upon the whole of it, and the wheat was the best of all."

A Weed-Puller.

Many troublesome weeds are best disposed of by drawing them out by the root, a slow but thoroughly effectual process. Mr. Julius Miner sends to the *Agriculturist* the sketch of an unpatented implement long used by him for taking out the Burdock, and other very troublesome and tenacious roots that infest our fields. It will do good service with all weeds that have a long tap-root. It consists of a stout stick, $3\frac{1}{2}$ feet long, to which is

fastened an iron trident or three-pronged piece, the teeth of which are $2\frac{1}{2}$ inches long. Or the whole length may be made of iron. A block 3 to 4 inches thick is bolted to the under side of the handle about 6 inches from the points. This serves as a fulcrum when prying out the roots. A cross-bar 8 inches long is attached, for conveniently thrusting the implement with the foot down to the root. When thus placed, a moderate amount of force at the end of the lever will lift a strong root entire.

A Horse-Cleaner.

F. W. Stump, Wayne Co., recommends to the readers of the *Agriculturist* the simple implement shown in the annexed engraving, for cleaning horses in muddy weather. It is made of a strip of $\frac{1}{4}$ inch board, 9 inches long on one edge, 7 inches on the other, and 3 or 4 inches wide. A convenient opening for the hand is shaved out on each side, and a hole bored through the square end by which to hang it in the stable. He uses this instead of a currycomb or card for removing dried mud from horses which have been used in wet weather. The currycomb is objectionable; its sharp points are too harsh for the tender skin of the horse. This implement followed by the brush, will answer a very good purpose.

Growing Carrots—Mulching.

No intelligent farmer doubts that the carrot is one of the most valuable roots that can be raised for stock. For horses, to alternate with oats or ground-feed, they are excellent, being nourishing and at the same time keeping the system free and in good order. Indeed, for horses which do only the lightest kind of work in Winter, carrots and potatoes and hay make a very good diet. When Spring opens, let one mess of oats per day be substituted for one of carrots or potatoes. They are excellent food for milch cows and oxen.—The cultivation of a crop of carrots is a simple process. A rich, loamy soil is preferable to strong, clayey ground. It should be thoroughly enriched, using old manure if it is applied the same year. A better way is to manure heavily the year before. Break up the ground thoroughly with plow or spade. Let this be no surface work. Thrust down the plowshare to the beam, or the spade its whole depth. This is the only way to avoid "fingers and toes," and to get long, large, well-formed roots. Harrow the ground until smooth and thoroughly pulverized; plant $\frac{1}{2}$ inch deep in drills, two or two-and-a-half feet apart, for field tillage, and eighteen inches for garden culture. This part of the work is greatly expedited by using a seed sowing machine. About two pounds of seed per acre will be needed. From the middle of May to the first of June, is the right time to put in the main crop. For early use, the best variety is the Early Horn. For late Winter, the Long Orange is a great favorite. The Altringham is thought to be hardly inferior to the last.

As soon as the plants are up, go through the rows, and thin out to from four to six inches apart. Keep the cultivator or hoe in motion, to suppress all weeds, and to keep the ground light and loose. This will also greatly help on the vigor and growth of the plants.

A writer at Lexington, Mich., adopted a good plan which he thus describes: "The carrots, thinned and hoed, grew finely, and I now began to think what to do to keep the weeds from springing up again. I remembered having read in the *American Agriculturist* something about mulching apple trees and newly planted shrubs; also I remembered, that last Summer I had some potatoes in my garden—the smallest spindling tops you ever saw—and having some spare stable manure in the Spring, I took it, after hoeing my potatoes, and covered the ground between the drills, and the potatoes improved rapidly and turned out a fair crop; so I now took stable manure and spread between the rows of my carrots. It did not dry up, as the dews and rain kept it moist, and the carrot tops soon covered it; with every shower the strength was carried to the roots of the carrots, and it was farewell to weeds."

In the Fall, as soon as the leaves begin to turn yellow, they may be taken up, cutting off the tops an inch above the crown, and storing away in sand in a cool cellar or a root-house. The tops are of value for feeding. Our correspondent says: "About the middle of October I began to think, what shall I do with this heavy growth of tops? Having had some experience in their worth as food for horses and cows, I took a scythe and mowed, from day to day, and gave them to two colts, feeding three times a day all they would eat up clean: the tops lasted between three and four weeks. Having but 3-16ths of an acre, this may seem fabulous, but it is true, and the colts improved much in flesh. I came to the conclusion, that as to quantity and qual-

ity, carrot tops exceeded any other green feed I was acquainted with." For Spring feeding, the roots may be in pits out of doors, covering the heap with six inches of straw set up endwise, and a foot or eighteen inches of soil laid on smooth so as to shed rain. The same writer gives the following expenses and profit on three-sixteenths of an acre devoted to carrots:

To plowing and raking ground.....	\$1 00
To seed and planting.....	88
To twice hoeing.....	62
To thinning.....	63
To mulching.....	1 00
To cutting tops.....	1 00
To digging and putting in cellar.....	3 50
Total cost ($4\frac{1}{2}$ cents per bushel).....	\$8 63

CONTRA.

By 192 bushels carrots at 25 cents.....	\$48 00
By 3 weeks' feed for two horses on carrot tops at $37\frac{1}{2}$ cents each.....	2 25—\$50 25
Profit on 3-16ths of an acre.....	\$41 62

Although this might not be reached in field culture on a large scale, it shows conclusively that it will pay abundantly to add an acre or two of carrots to the Summer crops.

Onion Culture—Hints to Beginners.

The unusually high market price of onions during the past season, will doubtless stimulate many who have had no experience, to go into their culture. No one should undertake to grow them without making up his mind to give the crop all the attention it requires. It is generally a paying crop, but one also which requires a great deal of labor, and unless this can be given, and just at the time needed, the attempt will result in disappointment. To grow onions successfully, requires a certain amount of experience, and we would not advise any one who is without this, to attempt the culture upon a large scale. In the first place the greatest care should be taken in the selection of the seed. This should only be obtained from reliable sources. Unless the seed has been saved from well grown onions, it will produce poor results, for no after-care will produce a good crop. The Large Red, Oval Red and Yellow Danvers are all good keepers. The White Portugal brings a good price but does not keep well for Winter use. Three or four pounds of seed are required for an acre. Onions require a good strong soil. If possible, land should be selected that has been previously used for some hoed and manured crop; if not rich it should be made so by a liberal supply of manure. Well-rotted hog or barn-yard manure at the rate of 20 or 30 loads to the acre is used, and deeply plowed in and then a top-dressing of 150 or 200 bushels of ashes is harrowed in. The soil must be thoroughly pulverized by the harrow, and afterward carefully raked with a large garden rake. It will be found to facilitate working, to lay off the ground in beds of about a rod in width. The sowing should be done as soon as the soil is dry enough to work, the earlier the better. The seed is most readily sown with a drill, in rows 12 to 13 inches apart, covering $\frac{1}{2}$ inch deep. In absence of a drill, mark furrows with a hand marker, and sow as evenly as possible by hand, and let a boy follow to cover with the feet. After the seed is sown, the ground should be rolled with a hand roller. As soon as the onions are up enough to allow the rows to be seen, an onion hoe should be run between the rows, lightly stirring the soil, and a few days after the rows must be weeded. This is the most tiresome part of the work, and is usually done by boys, who crawl along on their knees astride of the row, and remove every weed from among the onions. The weeds have to be constantly fought, and the hoeing and weeding must

be repeated as often as they show themselves, for the success of the crop depends in good part upon thorough weeding. Where the seed is properly sown, but little thinning will be needed, but where they stand too thick, they should be thinned to about three inches in the row. Very full details will be found in the Onion pamphlet, published at the office of the *American Agriculturist*. See Advertisement.

Sugar from the Beet.

The question whether sugar can be produced from the beet root in this country as in France, is in a fair way of being definitely settled. Hitherto, after many costly experiments, it has been supposed that owing to the difference of climate, soil, or other undetermined causes, the attempt would be fruitless. We learn from the Valley Farmer, that during the past year Mr. Belcher, a large sugar refiner in the West, has been testing the matter again on land contiguous to the Illinois Central Rail Road, with seeds of various kinds of beets procured from Europe. His success is reported as very encouraging. The Agricultural Societies of Illinois and Iowa, aided by the Ill. Cent. R. R. Co., are lending their aid for further trials. An arrangement has been concluded with a company of Germans to establish a refinery on the farm of W. H. Osborn, President of the R. R. Co., at Chatsworth, Ill., and fifteen hundred acres are to be cultivated with the beet the coming season. In France the production of sugar from the beet has become of national importance, amounting in a single year to nearly 150,000 tons. The present is a most favorable time for the initiation of the enterprise in this country. It is quite likely that the above movement gave rise to the specious advertisement of the "New Oriental Sugar Plant" noticed in the *Agriculturist* last month.

Late Sowing of Clover.

"J. H. A.," Mifflin Co., Pa., sends to the *American Agriculturist* the following suggestions: "In this section our best success with clover has been when it has been sown after the ground had become quite well settled in Spring, and the weather warm enough to germinate seed quickly. We believe that the sooner any seed germinates after being placed in the soil, the more certain will be its growth. It is known that many kinds of seeds can not remain more than a few days in the ground during weather unfavorable to germination, without losing their vitality. The seed of clover is so small, and the germ so minute, that however unfavorable the effect of too early sowing upon either, it is almost sure to escape the notice of the farmer; otherwise I think sowing this seed in March, in this latitude at least, would now be almost abandoned.

We may, in some measure, judge of the injury done to the seed of young clover by a month or six weeks of weather unfavorable to the germination or growth, by considering the natural requirements of the plants. I believe no field crop is more benefited than this, by warm showers and sunshine. Even after the first season's growth, and being quite well rooted, it requires what we call the best growing weather to bring it to perfection—and under such circumstances it is a plant of rapid growth. Clover during a cool Summer always looks yellow and sickly, and is sure to be a short crop. From this, may not the farmer conclude that the alternate freeze-

ing and thawing of the ground, and the consequent swelling and shrinking of the seed, and the frequent starts and checks the young plant must receive during four to six weeks, greatly injure the plants just at the start, which can not be remedied by after-treatment, as the "set" will be too thin.

Experience with Millet.

Abraham Herbein, Berks Co., Pa., writes to the *Agriculturist* that thirteen acres of corn replanted twice, last Spring, were finally made worthless by the cutworms, and so about the middle of June seven acres of the plot were sowed with millet (Hungarian Grass). The soil, a black shale, was rather thin in some places, and therefore easily affected by a drouth which occurred from the setting to the ripening of the seed. On these spots the millet grew only about ten inches high, and shriveled before it was cut. Where the soil was deeper, it yielded at least three tons of cured hay per acre. From the whole seven acres, twelve tons were harvested. About one hundred bushels of seed were obtained from this, much less than would probably have ripened, had the weather been favorable. The straw, after being threshed by a machine, was eaten by cows and other stock as readily as the best meadow hay. The seed is considered by him equally valuable with rye or corn for cattle and hogs, but not so suitable for horses.

The remaining six acres of the above field were sowed with buckwheat, which returned only thirty bushels. It was injured by dry weather, and nipped by early frost. Mr. Herbein thinks that millet will generally be found a safer crop than buckwheat to replace a failing crop of corn. It ripens sufficiently early to be followed with winter grain. He also intends to substitute the millet for oats this Spring, last year's oat crop having been a failure from the ravages of the aphides or yellow plant lice.

Seeds by Mail—The New Law.

The reduction of the postage on seeds and cions to one cent an ounce, is one of the best reforms of the age, and is giving a new impulse to horticultural improvement throughout the country. It is especially helpful to those who live in the thinly settled districts, remote from the large towns or cities in which seed stores are kept, and in the suburbs of which most of our nurseries are located. It virtually puts down the best seed stores in the country at the door of every subscriber to the *Agriculturist*. He has only to look over our advertising columns and order what he wants by letter. He gets first-rate seeds for about the same price he could buy them in the city, without the trouble or expense of the journey. Though he live in the new settlements of the west, he can procure the best seeds and cions grown in the East, at a trifling postage expense.

Its tendency is to make these articles both cheap and good, for it favors competition and makes every seed grower directly responsible to the purchaser. Every man who has a choice variety of vegetables or fruits, has an inducement to multiply it, for, if he will advertise, he has a ready market for the seeds or cions at the nearest post office. Small plants and trees, if properly packed, will go safely by mail. Any one who examines our advertising columns will see that this business is largely on the increase.

P. S.—The above was prepared for last month's paper, but crowded out. Since it was

written, a new postage law has been enacted, according to which, as we understand it, the rates after July 1st will be: 2 cents on one, two, or three circulars in the same envelope; and on seeds, cuttings, etc., 2 cents on any weight up to four ounces, and 2 cents for each additional four ounces, or fractional part of four ounces. This will be a reduction, for on four ounces or eight ounces the postage will be only $\frac{1}{2}$ cent an ounce. The new rates will therefore facilitate the sending of large parcels, and heavier seeds. A whole pound will go for 8 cents to any part of the United States and Territories.—The present rate (1 cent per ounce) continues until June 30. Many of our subscribers sending for seeds, have made themselves needless expense, by putting 3-cent stamps upon their envelopes, where only 1-cent stamps were required, according to the directions plainly given. When practicable, we have removed the extra stamps, and put them inside of the envelopes, but this could seldom be done without defacing the stamps.

How Much Seed per Acre?

The following suggestions condensed from an article in the Mark Lane Express (England), apply equally well on this side the Atlantic. Land naturally poor, or temporarily reduced in fertility by over-cropping, requires thick seeding. Soil in low condition can not force vegetation to any extent, therefore little or no tillering takes place. Consequently each kernel will produce but one stem, and, when thickly seeded no more are required or can find room to grow. The opposite of this is the ease with rich soil. The increase by tillering will far exceed the difference made in the quantity of seed generally put on. Suppose five bushels of oats per acre are to be sown on poor land, and two bushels on good soil. If each plant of the latter should throw out three tillering stems there would be a heavier yield than on the thickly seeded portion. But where the tillering process is fully developed as on the wheat plant in rich ground, the average will far exceed three collateral stems. Of course, every allowance should be made for liability to loss from other causes, as worms, insects, unfavorable weather, etc. A table showing the proper amount of various seeds per acre, to be sown, including the variations to be made on account of difference of soil, was published in the Nineteenth Volume of the *American Agriculturist*, page 139 (May, 1860).

Feeding the Chinch Bug.

Mr. R. F. Roberts, of Racine Co., Wis., sends to the *Agriculturist*, the experience of a farmer in that County. "Two years ago he seeded down a piece of land sowed to oats. The grass took well and the oats gave a large yield of excellent quality, while all the rest of his oats and his wheat suffered greatly from the ravages of the chinch bug. Last Spring he seeded down another piece sowed to oats, which yielded a large crop of heavy grain, while a plot of wheat sowed beside it was scarcely worth cutting. His conclusion is: that the chinch bug feeds on the tender grass, and while they are doing that, the grain matures so that it is beyond their power to injure it. He noticed that when he cut the grain on the plots seeded down, the bugs appeared as thick as they were on the other fields. This coming Spring he is going to sow grass seed with all his grain crops, using two thirds

the quantity of grass seed commonly sown, when seeding down meadows, and of wheat and oats the same quantity as if no grass seed was sown with them. He prepares his seed wheat by soaking in strong brine and drying with slaked lime." [The lime, and the brine, are always good for seed wheat and seed corn.—Ed.]

To Sweeten Butter-Firkins.

Mrs. Arch. Cooper, Racine Co., Wis., sends the following directions to the *American Agriculturist*: "Before packing butter into new firkins, put them out of doors in the vicinity of the well, fill them with water, and throw in a few handfuls of salt. Let them stand three or four days, and change the water once during that time. Butter-firkins should be made of white oak, and this process effectually takes out the acid contained in that wood, and makes the firkins sweet. If the butter is well made and rightly packed, it will keep good all Summer, even if the firkin be kept in store above ground. To cleanse old firkins in which butter has been packed and left exposed some time to the air, fill with sour milk, and leave standing twenty-four hours; then wash clean, and scald with brine. This makes them as good as new.

Questions About Plants and Flowers.

We have several letters giving descriptions of plants and asking us the name. Though we may be able to give a tolerable guess, it is not possible to name a plant in this way with any degree of accuracy. Those who wish for information of this kind, which we are always ready to give, should send us a specimen for examination. We can sometimes recognize a plant from a mere fragment, but it is better in all cases to send a complete specimen, which should include some of the flowers; the seed, ripe or partly so; the upper leaves; and if the lower leaves are different in shape, one of those also. The specimens should be dried by laying them in an old book or by putting them between several thicknesses of newspaper with a heavy book laid on to press them. Use only pressure enough to keep the leaves flat while drying.

Preparation of Furs.

Several of our Western readers have asked how they can prepare the skins of animals for use. We have not been able to get much information from the fur dealers, who wish to keep the secrets of the trade to themselves. We understand, however, that the dried pelts are put into tubs with a quantity of rancid butter, (probably rancid is used because cheaper than fresh,) and they are then trampled by the feet until they become soft and pliable; after this they are trampled with saw-dust—mahogany being preferred—to remove the grease. The furs are then ready to be made up. We find the following in the California Farmer. It will be observed that the directions do not give the amount of water to be used; probably enough to well cover the skin will answer. We suppose that this process is intended for fresh skins: Take one pound of alum to five pounds of hide, a double handful of salt—all of which dissolve in warm water. Put the skin in and let it stand for from twenty-four to forty-eight hours; then take out and dry, and it is done. To tan with the hair off, the skin must be first soaked in strong lime-water till the hair comes off; then treated as directed for tanning with the hair on.

VEGETATION IN THE SOUTH-WESTERN TERRITORIES.

Sketched and Engraved for the American Agriculturist.

One accustomed only to the vegetation of the Northern States is struck, as he travels southward, with the new forms which meet his eye, giving new features to the landscape. If he continue his journey until he reach the Territory of Arizona, upon the borders of Mexico, he will find a vegetation entirely unlike that which he left at the North. Instead of green fields, the parched soil bears only a few scattered tufts of grayish grass, and in place of leafy forests, in whose shade one might find shelter from the burning sun, there are the strange leafless trunks of the Cactuses, whose singular appearance and spiny branches repel rather than attract the traveler. Above we have sketched and engraved a scene in this barren territory, which well illustrates the appearance of the region where the plants of the Cactus family seem to attain their greatest luxuriance. These plants are peculiar to the American Continent, and are represented with us by the Prickly Pear, which is found as far North as Massachusetts and Wisconsin; but no one, from seeing this, or even those which are cultivated as greenhouse and parlor plants, can form an idea of the peculiar effect produced where the mass of the vegetation is made up of larger plants of this family. One of the most striking characteristics of these plants is, that they bear no leaves, but the green rind of the stems does their work and answers in place of them. Instead of leaves they bear tufts of spines or thorns, the number, size and shape of which vary with the different species. Some of these spines are several inches in length, either straight or hooked at the end; others are small and hair like, but all

sharp and capable of inflicting annoying or dangerous wounds. These Cactus plants are wonderfully adapted to the region in which they live. But very little rain falls there, and this only during a few weeks, all of the rest of the year being a continued drouth. While in our moist climate, plants expose a great surface of leaves in order to facilitate evaporation, there they are constructed on a plan which exposes the least possible surface—they are all cylinders or spheres. When the short rainy season comes on, these plants start into life, make their annual growth, and flower, and produce fruit. The dry season soon follows; the whole country, under the influence of the sun and parching atmosphere, becomes burned and barren like a desert. All the tender plants which the rain had called into existence, perish; then the Cactuses go into a dormant state; they have no leaves to wither and fall away; they close up the pores of their thick skin, and resisting the drying influences around them, they retain their juices until the next rainy period awakens them to activity again. Notwithstanding the unlovely aspect of the plants themselves, they produce flowers which are often of great beauty. Some of the Cactus family are among the chief ornaments of our green-houses. We have seen them in the wild state when the desert literally “blossomed as the rose.” Their fruits, too, are generally pleasant and often delicious, some being very much like figs, and others having a fine fruity flavor. The largest plant represented in the engraving is the Giant Cereus (*Cereus giganteus*), which grows to the height of 40 to 60 feet, sometimes rising in a single column, but more fre-

quently branching and throwing out great up-turned arms. Though this is, from its size, the most conspicuous, there are others, a few of which are represented in the foreground, which are not less noticeable. Some of these are mere spiny balls, others branching and tree like, others in shape like the Prickly Pear, only as tall or taller than a man, and all of them so provided with thorns that the careless traveler soon learns to respect if he can not admire them. We know of nothing more strange and wild than to see, as we have often done, a landscape in which these outlandish plants form the chief vegetation.

Trenching Grass Plots or Lawns.

There are good reasons for this. A lawn is to be planted more or less with trees, and they will grow vastly better in a deep soil than in a shallow one. They will strike their roots down deep, and spread them out wide in search of food, and their rapid growth will show their keeping. Even small trees set in such ground will soon outstrip large ones set in shallow soil, and will always be handsomer. A lawn is also to be a carpet of grass. If it be well trenched, the grass will be vigorous and green in Spring, Summer, and Fall. It will not turn brown and burn out in the first “dry spell.” The moisture from below will continually rise to keep the roots fresh. The grass will bear frequent mowing and rolling, and will constantly improve. If any one doubts the good effects of trenching, let him compare a lawn so treated with one only surface worked, and he will be convinced.

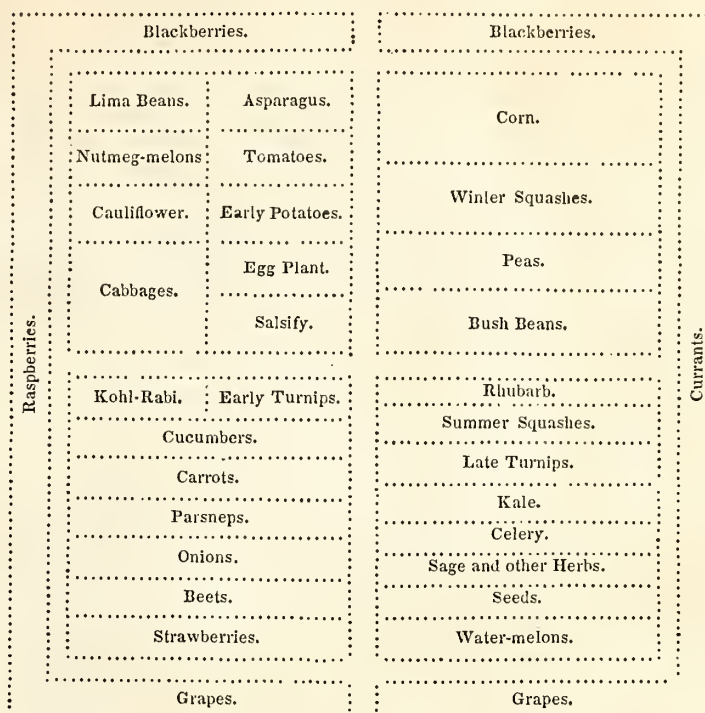

Spring Salads.

Salads are relished by most persons the year round; but in Spring particularly, when new vegetation is putting forth, they are regarded as especially seasonable. They look refreshing upon the table and are acceptable to the palate. Water-cress is among the earliest of the salad herbs, but as this requires a constant stream of running water for its successful culture, it is not within the reach of most persons. Corn Salad, or Feticus, is a very popular salad with Europeans and is generally cultivated for our city markets. It may be had very early, and is very readily raised by sowing in autumn and covering with a slight winter protection. It is a mild, tender herb, without much taste of itself. Mustard makes a good salad. It may be sown broadcast as soon as the ground is thawed, and should be cut or pulled when 2 to 4 inches high. Cress or Peppergrass is a very common salad, either used by itself, or mixed with Lettuce. It should be sown very early upon a light quick soil, and cut for the table as soon as large enough. Lettuce is however the universal and popular salad plant. Some of the hardy kinds may be sown in Autumn and covered during Winter with straw or coarse litter. Sow very early in the Spring. It is a common custom to plant rather thickly in rows and allow the plants to crowd one another—in this way a partial blanching is effected. Lettuce can only be had in perfection by growing the plants singly. To have it early, sow in the hot bed or in boxes in the house, and as soon as the weather will allow, transplant in rows, a foot apart each way. The soil should be highly manured with well rotted compost and every means used to ensure a rapid growth; hoe frequently and give liquid manure. Slow growing plants will be without the tenderness and crispness so desirable in lettuce. Sowing in the open air may be done as soon as the ground can be worked. For varieties, we prefer the Butter, Ice Drumhead, and Neapolitan Cabbage, (the latter is on our seed distribution) though almost any sort is good, if well grown as above directed.

Lima Beans, and How to Plant Them.

Few products of the garden are more acceptable than Lima beans, cooked green, and also when ripe. For some reason many persons fail in growing them well, however. They either do not come up at all, or they make a weak or sickly growth. If planted like the smaller varieties, with one to three inches of earth over them, and this perhaps packed down with the hoe and by rains, the cotyledons or seed-leaves can not force their way to the surface, and they rot. The soil should be dry, loose and warm, and the covering very light—hardly more than just to hide them. It is best to raise hills of moderate height, and set poles before planting; then stick the beans in with the eye down, and leave them at or just below the surface. A very good plan is, to prepare a small bed of light, warm soil, on the south side of a tight fence, and stick in the beans all over its surface, two inches or so apart, and sprinkle on a very light covering of sand, or fine soil. If needed, a sprinkling of water may be given often enough to keep the soil damp. If a chance cold night occurs, throw an old blanket or mat over the bed. When sprouted, before rooting, transfer to hills. A still better way, perhaps, is to start the separate beans in bits of sod, and transfer

these to the hills. See particulars under "Hot-bed Substitutes," on page 99, April *Agriculturist*.

How I Laid out My Vegetable Garden.

[The above plan, together with the notes below which accompanied it, are to be taken as suggestive merely. The size, form, and location of a garden will in every case determine the plan. The appearance of a garden may often be improved by a proper arrangement of the tall and low growing plants.—ED.]

EDITOR of the *Agriculturist*: Having long looked forward to retiring from business in the city, to a farm in the country, I a few years ago so far secured my wish as to obtain a plot of ground, about 100 feet square, upon which to realize my long cherished desire to be a cultivator of the soil. I commenced without experience, and of course made many failures before I attained even tolerable success. I will not trouble you with an account of my failures, further than to state that they were mainly due to sowing too early or too late, and to using either too much or not enough seed. My object is to give a plan of the disposition of my beds—not because I think it the best that can be adopted, but it is easier to alter a bad plan than to originate one altogether, and I think an inexperienced person, as I was, will go to work more readily if he have a map of the route some one has traveled before him. The plan hardly needs explanation. There is a walk all around, 2½ feet wide, leaving a border of five feet next the fence. Two principal walks, five feet wide, cross each other at right angles. These are all the paths that are really needed—more would waste too much space and give extra trouble in keeping them in order. No raised beds are made, as these, where the ground is naturally or artificially drained, are needless. By avoiding small beds, the soil can be well and cheaply put in order by the plow and harrow; I used a subsoil plow and found a decided advantage in it. My hot-beds were on the space occupied afterwards by watermelons, the manure used in them being forked in for the crop. Not having a seed-sowing machine, I constructed a marker like a large wooden rake, the teeth of which

were V-shaped, and so arranged as to be moved; by means of this I could mark out rows at distances of 6 inches, 12

inches, or 18 inches, which are the spaces most generally required. The marks being made, the seeds are sown by hand and then covered by drawing the earth over with the back of a rake or with the foot. On April 15th, I sowed spinach, onions, early turnips, cabbages, early beets, peas, salsify, and a few carrots, and planted early potatoes. Spinach, radishes, etc., are not down on the plan; these I sowed in the spaces between hills of potatoes and cucumbers, and wherever there was a spare spot. The 1st of May I made a sowing of most of the other seeds; on the 15th I set out the plants from my hot-beds, and put in melons of

all kinds and late squashes. June 20th, the late beets, turnips, peas, and sweet corn for succession, were sown. As the results of my labors I had better and fresher vegetables than could be purchased in market, the great pleasure of working the garden, and the great satisfaction of enjoying the fruits of my own toil. C. H.

Some less Known Garden Vegetables.

Correspondents ask us for brief descriptions of several of the garden vegetables, the seeds of which are found in the catalogues, but which are not generally known and cultivated. Many of them are mere flavoring herbs, and others are articles of food which are only obtained with considerable trouble, and their cultivation is mainly confined to the professional gardeners.

Artichoke.—The plant usually known by this name in this country, is the *Jerusalem Artichoke*, a kind of sunflower, which bears tubers somewhat like a potato. The *true* Artichoke is nearly related to the thistle. It bears an enormous thistle-like head of flowers, which are surrounded by a cup of thick fleshy scales. This is the portion which is eaten. The seed is sown in drills, the plants thinned to a foot apart, and cultivated during the first season. During the Winter the plants are earthed up or covered with litter, and in the following Spring they are set out in clumps or hills of two or three plants, the hills 4 feet apart each way. They need a very rich soil. The heads which are produced the second year, are cut as soon as they are fully formed, and before the scales begin to open. They are boiled and served with drawn butter. The crowns need protection in Winter. Old plants throw up several suckers which may be taken off and planted to increase the stock.

Burnet.—A hardy perennial plant, the young and tender leaves of which have a taste and smell like cucumbers. Sow in Spring and thin to 6 inches in the row.

Cardoon.—Is a plant much like the Artichoke, the leaf stalks of which, after being blanched

like celery, are much used in France in stews. The seeds are started in a seed-bed. The young plants are afterward set out in trenches and treated like celery. It is not our favorite.

Collards or *Coleworts* are merely young cabbages not headed. They are used as greens.

Roquette.—A hardy kind of Cress or Pepper-grass; if planted in early Fall and covered during Winter it yields very early Spring salads.

Scorzonera.—A plant closely related to Salsify and grown in the same manner. See page 85, March *Agriculturist*. The root before it is cooked should be scraped and soaked for some hours in water to remove the bitterness.

Skirret belongs to the parsley family. The roots are used in the same way as Salsify. They have a peculiar taste, not generally relished.

For the American Agriculturist.

Beans and Peas—Use for Old Hoop-Skirts.

I planted my pole beans, Limas included, in hills 20 inches apart, the rows 3 feet apart. On the outside ends, and in the center of each row, I inserted a sharp pointed stake about 8 feet long, driving it firmly into the ground, say 15 inches. The rows were 50 feet long. Next I fastened a small wire to the three sticks—about six feet from the ground, hauled it taut, and secured it to each stake by a single nail, like a telegraph wire. Two small sticks were driven *very slanting*, one on each side of every hill. A ball or two of common wrapping twine completed my arrangements. I tied the twine to the outside stick, passed it twice over the telegraph wire, down to the next stick, over the wire again, and so on to the end; thus each hill of beans had two or three strings to climb up. They took to the strings freely, soon clasped the wire, and were safe from all ordinary storms. Shall I tell you Mr. Editor, what wire I used? Don't smile; it was discarded hoop skirts, heated in the stove to destroy the temper of the steel wire and take off the cotton wrapping; and I assure you, that all who saw my beautiful rows of beans swaying gracefully in the wind, were ready to agree cordially with the "Old Bach" who writes this, that the aforesaid wire was never before put to so useful or ornamental a purpose. I used my old discarded bean poles and strings to support my peas, sticking the poles four feet apart on each side of the rows of peas. Four horizontal strings tied to the poles at proper distances, one above the other, completed the supports. It answered beautifully, and was quickly imitated by my neighbors. For the peas a much stronger string is required than for the beans. Fine wire would be better and would last for several years. J. H. Dodgeville, Wis.

Economizing Room in the Garden.

Where space is abundant, a few extra feet are of little account, and the various plants may be cultivated without particular regard to economizing room. But thousands of our readers have only a limited area to improve, and need to make the most of it. Much room will be saved by dispensing with beds for vegetables. Let them be simply planted in long rows, extending across the space devoted to the purpose. No dividing walks are needed between the various sorts. One walk, the length of the garden, with rows extending on each side, is a good arrangement. Several plants, as radishes, lettuce, etc., may be scattered among

hills of young vines, and by a succession, as late corn after early peas, turnips after early potatoes, etc., much more produce can be realized.

Make a Strawberry Bed.

It is but little trouble to make a bed. Plants are cheap and the postal arrangements are such, that those living far from nurseries can readily get by mail plants of enough choice kinds for a beginning. Any good garden soil, enriched with old manure, will raise good strawberries. If there are but a few plants to start with, the object should be to multiply them as rapidly as possible; set them out 18 inches or two feet apart each way, prick off the blossom buds if any appear and keep free from weeds. Runners will be thrown out and form new plants, and a dozen plants will in a year multiply enough to set out a very large plot. A stock of plants having been procured, make beds 4 feet wide, with suitable alleys between. Three rows of plants can be put on the bed, eighteen inches each way, which will bring the outer rows 6 inches from the edge of the bed. In setting out the plants, the old and partly decayed leaves and all runners should be removed. It is the custom of some good cultivators to cut off the roots for one third or one half their length. In planting, spread the roots well and press the earth well around without covering the plants. It will pay to plant in the manner recommended on page 309 of the *Agriculturist* for 1861. A mound of earth is made in the hole, the plant is set upon the ground with its roots carefully spread out over it, and the hole then filled with earth. This will be readily understood from the

engraving. We planted in this way a bed of over a thousand plants without losing one.—There are two ways of growing strawberries. One is to keep all the runners pinched back as fast as they appear. In this way the plants form large stools and continue in bearing 5 or 6 years. Most varieties do well in this way, but Wilson's Albany, from its manner of growth, is not so well suited for this kind of culture. Another, and the most common way is to let the runners grow, and a bed of this kind will give one full crop and a partial one, when it is spaded up. There of course should be another bed ready to succeed it. For varieties see p. 101, last month.

Celery.

The great difficulty in raising this delicious product of the garden, is in starting the plants. The seeds are slow in germinating and the young plants are very delicate. There are several kinds, but perhaps none better than the early and late White Solid varieties. For the earliest, the seed should be started in a hot-bed. A very gentle heat is all that is required. The manure for this hot-bed should be mixed with plenty of old leaves, and the soil in the bed should be 10 or 12 inches deep. The seed should be merely covered with soil and the bed should be shaded by mats until the plants are well up, and then they should be protected from the sun during the hottest part of the day, and have plenty of air. Water and weed the bed carefully. Thin out the plants to an inch apart, when an inch high transplant to another bed. For out of door sowing, select a place where the bed will be shaded by 10 or 11 o'clock, burn

the surface over by a fire of brush or straw, and then sow the seeds and lightly rake them in. If a shaded place is not at command, cover the bed with leafy brush, or set up a screen of some kind, and keep the bed well watered. In weeding or stirring the soil about the young plants, be careful to do it only when both soil and plants are dry. When three or four inches high the plants should be placed in trenches; these should run north and south and be one foot wide, and two feet deep and about 4 feet apart. Six or 8 inches of well rotted hog or barn yard manure should be put at the bottom of the trenches; add 6 inches of soil, and spade the whole up thoroughly. The trenches may be prepared for sometime before the plants are large enough to put out. When the plants are large enough they may be transplanted to the trenches; fork over the soil at the bottom of the trench and put out the plants, a foot apart. If the young plants are disposed to form a large tap root it should be shortened. It is well, if the weather is hot, to shade the plants a few days after transplanting, by laying boards over the trenches, while the sun shines hotly. As the plants grow, soil is to be carefully filled in below the green leaves from time to time. A light, sandy soil, with plenty of manure, is better for celery than a heavy, clayey, or wet soil.

Cauliflower.

This is one of the most delicious vegetables the garden affords, though many fail in raising it. The requisites are good seed and good soil. If the seed is not of a good stock no after culture will produce satisfactory results. We have grown Early Paris, Thorburn's Nonpareil, and Large Asiatic and had satisfactory results from each. When very early cauliflowers are desired, the seed is sown in Autumn, and the partly grown plants are wintered over in the cold frame. Seed for a later crop may be sown now, either in a frame, or in an open bed. The seedlings are raised in the same way as cabbage plants. The bed to which they are transplanted can hardly be too well prepared. Deep working, and a plenty of well decomposed manure, are essential to the growth of the plants. Set out at two feet apart each way. It often happens that the growing point or bud of the cauliflower is enclosed by the base of the leaf stalks and is prevented from developing. Such plants will never make a head and should be rejected. The Cauliflower is subject to the same enemies as the cabbage, and needs the same frequent hoeing. Should a drought occur give water and stimulate with liquid manure in moist seasons. The heads should be cut when fully formed, and before they become loose.

Planting and Pruning the Grape.

Several letters have been recently sent to the *Agriculturist* inquiring about pruning the vine. It is now altogether too late to prune old vines. We shall endeavor to make the whole matter plain at the proper season. A few hints concerning the treatment of newly planted vines will be timely. The vine should be one or two years old, when planted. Some of the best cultivators prefer to begin with those only a year old. A vine of this age should be cut back to two or three buds, and after the buds start, all the shoots but the most vigorous one, should be pinched off. Place a stake by the side of the vine to which it is to be tied. As side branches spring from the main shoot, pinch them

back to a single leaf. The object of the first year's cultivation should be to make as strong a main shoot as possible. In Autumn the season's growth is to be cut down to two buds. If a vine two years old is planted, it should be cut back, and only two shoots be allowed to grow. These are to be trained to stakes, and to have the side shoots pinched off, as directed for the one-year-old vine. In the Autumn there will be two strong canes, which are to be cut off to three feet in length. The vine treated in this way becomes vigorous, and is in proper condition for the favorite renewal system of pruning.

The Currant Worm.

It does not seem possible to exterminate this pest, but it may be kept in check. Deluge the bushes with diluted whale oil soap, applied through a garden syringe having an upturned nose. Mind to give them a good soaking underneath, as well as overhead. If any one has not the soap at command, let him burn tobacco or sulphur, in an old pan, setting the dish under each bush for several minutes. Let it consume slowly, to make as much smoke as possible. Or this: Make a smudge of old scraps of leather, and let it lie under each bush until the entire foliage is filled with a cloud of smoke. This will be more efficacious if a little powdered sulphur is thrown in. Be careful not to scorch the leaves.

For the American Agriculturist.

Use Large Potatoes for Seed.

The question of the best kind of seed potatoes is not settled for all parts of the country. It is settled among market gardeners of large experience who have to dispose of their crop in the cities. It is important for them to raise the largest number of merchantable potatoes from a given quantity of seed, upon a given area. They have no home market for small potatoes, and do not believe in keeping them for seed. With the farmer at a distance from market, the case is different. He raises his crop mainly for home consumption, and what are not consumed in the family are fed raw or cooked, to stock. Small potatoes weigh more to the measured bushel; they are as nutritious, weight for weight, as large ones, and if they yield as well, he is satisfied. He does not stop to consider the increased labor of harvesting, or the small value of this root for feeding stock in comparison with its value for human food. For the former use, they are not worth over twenty-five cents, and for the latter, are worth the market price, which is fifty cents and upward in this vicinity. [Good merchants are now, (April 10,) wholesaling in New-York at \$2.25 per bbl., and peach-blows and other common sorts at \$1.50 to \$2.—ED.]

In the suburbs of the city, especially on Long Island, potato growing is pretty nearly reduced to a science. Many of the farmers make this their main crop, and not a few raise two thousand dollars' worth and more, in a season. They plow in horse manure and plow deep. They select their largest potatoes for seed, quarter and plant the pieces in drills about fifteen inches apart, and prefer to have only four stalks in a place. The product is potatoes of very uniform marketable size, with few or no small ones. They require very little sorting, and the whole crop is turned into money at the market price. These farmers doubtless know what is for their interest, and ridicule the notion of planting small potatoes to realize from.

Farmers who do not make potatoes a special-

ty, may learn something from the large experience of these men. It is more profitable to raise potatoes for market than for stock, and with all the drawbacks for rot, potatoes generally pay better than corn in the old States, especially where farmers are within convenient wagon drive of a market. It looks reasonable that the body of the tuber should contain the strongest germs, and be most secure from rot. Possibly the continued planting of small tubers has a tendency to weaken the stock and to induce rot. This year a multitude of men that were upon the farm last Spring are in the tented field, and we shall want all the potatoes we can raise, to make breadstuffs cheap. Plant one more acre, and let the seed be large. CONNECTICUT.

For the American Agriculturist.

Notes on Bedding Plants.

BY THOMAS CAVANAGH.

At this season of the year, the markets are well stocked with beautiful flowers, principally house plants. These are grown in hot-houses, and forced into bloom, and many are tempted to purchase them by their showy appearance. But although beautiful for a short period, they soon cease flowering, and in most cases lose their leaves, much to the disappointment of the purchaser. The reason of this is, the sudden check they receive upon being removed from a very high temperature, to one much lower. As a general rule, a rapid growth makes a weak plant, and a slow growth makes a strong one. In purchasing plants the proper way is to make a list, go or send to some responsible florist, and let him select young and thrifty plants *not yet in bloom*. These when planted out, will go on growing, and when fairly established in the soil, will commence blooming and continue to do so during the Summer. Many experience difficulty in purchasing plants not yet in bloom, from not knowing the names and colors. The following is a list of some of the many favorites now in cultivation, and which from their cheapness may well be added to every private flower-garden.

ROSES.—*Hybrid Perpetuals*: Baron Provost, bright rose color; Giant de Battailles, crimson; Duchess De Cambaceres, bright rose, very fragrant; Jules Margottin, bright crimson; Madame Plantier, pure white; Caroline De Sansel, blush. The above flower at intervals only, during the summer.—*Monthly roses*, flowering all through the season: Hermosa, bright pink; Agrippina, dark crimson; Souvenir De la Malmaison, white changing to blush; Safrano, straw color; Devoniensis, white tinged with cream color; Archduke Charles, dark crimson.

VERBENAS.—Lady Palmerston, blue with a white eye; Ocean Pearl, maroon with a white eye; Mrs. Woodruff, bright scarlet; Philadelphia, striped white and crimson; Indigo, deep blue; Snow Wreath, white; Manetti Coccinea, striped white and scarlet, good for edgings; Adrienne, purple; Princess Clotilde, white, purple eye; Giant des batailles, crimson; Mrs. Field, deep crimson; Black Knight, dark maroon.

GERANIUMS.—Tom Thumb, scarlet; Hendersonii, white; Tom Thumb's bride, pink; Princess Royal, blush white; Variegated leaved Pennyroyal; Flower of the day, silver edged leaves, color scarlet.

LANTANAS.—Grand Sultan, red; Aurea, orange; Album, white; Mrs. Shale, pink.

HELIOTROPES.—Corymposum, lavender; Reine Des Heliotropes, dark violet.

FUCHSIAS.—Speciosa, pink; Princess of Prussia, crimson, and white; Madame Cornillon, crimson, double white centre; England's Glory, waxen sepals, crimson centre; Black Prince, dark purple; Folia variegata, variegated leaved.

SALVIAS.—Splendens, bright, scarlet; Amabilis, lavender blue; Patens, deep blue.

PETUNIAS.—General McClellan, finest double one yet raised, spotted crimson and white; Zouave, beautifully marked, pink and white.

DAHLIAS.—Sir Colin Campbell, crimson; King of Yellows; Negro, dark maroon; Amazon, yellow, scarlet edge; Celestials, violet; Mrs. W. Puget, pure white.—*Dwarf Dahlias.*—Little Negro, dark maroon; Snow Flake, white; Victor Hugo, crimson; Bouquet, blush; Golden Pheasant, yellow, edges tipped with red; Mr. Schwab, scarlet. There are other fine ones.

MISCELLANEOUS PLANTS.—*Ageratum*, flowers light blue. *Cuphea platycentra*, or fire cracker plant, curious shaped scarlet flowers. *Calceolarias*, or ladies' pockets, showy plants, but soon out of bloom. *Nierembergia Gracilis*, flowers light blue. *Gazania Splendens*, showy flowers, of a bright orange, white and brown. *Bougardias*, bright scarlet. *Lobelia Speciosa*, color blue, fine for rustic basket. *Tropeolum*: Tom Thumb, scarlet. *Aloysia citriodora*, lemon scented verbena, delicate white flowers. *Feverfew* (*Pyrethrum*), double white, daisy like flowers. *Colius Verschaffeltii*, one of the new bedding plants which is not yet sufficiently well known to have a common name. The foliage is of a rich velvety crimson, the edges of a bright green.

Arranging the Spring Flower Garden.

Much enjoyment of the garden in Spring is lost, by having flowering plants scattered about over so wide a surface that they cannot be seen together. They thus fail of the fine effect produced when grouped near each other, and with some regard to color. The flowers of early Spring are few in number, small in size, and modest in coloring. They need bringing together, to have the benefit of each other's company.

For example: the Snow-drop is almost nothing if alone, and so the *Bulbocodium vernum*; but group them in clumps of a half dozen plants each, and they will command the attention of even Mr. Gadgrind. It is a good plan to set the crocuses in clusters of distinct colors, or in circles, making rings of the different colors—orange, white, blue, and the intermediate shades. The Hyacinths are larger and more showy, and can better take care of themselves, but even these do best in a bed by themselves, instead of being scattered about in places wide asunder. So of Pansies, and of the Primrose family, including the Polyanthus and Anemula. We were much pleased last Spring, in seeing an oval bed of the Polyanthus, arranged with the different colors in distinct circles. And here, let us add, that the common practice of setting these in the open, sunny border, is not a good one; they succeed best in a partially shaded aspect. The modest Liverleaf of the woods may be brought in to play an important part in the spring garden; also Blood-Root and other native plants. As to the sweet-scented violets, white, blue and double blue, we would set them in masses, but would also scatter single plants about here and there and everywhere, so that their delicious fragrance may regale the senses in all parts of the garden. A little forethought and planning will make many spring gardens much more attractive than they usually are.

Fig. 1.—ZINNIA ELEGANS.

Annuals for the Flower Garden.

Any plant which perfects itself within a year from the time it is sown, is an "annual," though the term is especially applied to those ornamental plants which have this peculiarity. These, though lasting but a season, comprise many of our most desirable flowers. Some of them grow with the greatest ease, while others require much care and attention. The hardy annuals, once sown, will perpetuate themselves without further care. The ripened seed drops, and remains in the ground over Winter, giving earlier and stronger plants than are produced from seed sown in the Spring. Among these hardy annuals which will grow from self sown seeds are: Larkspurs, Mignonette, Sweet Alyssum, Candytuft, Portulaccas, Gilias, Whitlavia, etc. The half hardy annuals, such as Balsams, Phlox Drummondii, China Asters, Clarkias, etc., may be sown in the open ground in April or early in May, while the tender annuals should not be sown in the open ground until the last of May or the first week in June. To have them early they may be started in the house in pots or boxes, or in a hot-bed. Many persons fail in raising annuals, from sowing the tender kinds too early, and from covering the seed too deeply. The seed is to be sown—not buried. Having prepared the ground by spading in well rotted manure, and thoroughly pulverizing and raking, mark out with the finger, or a pointed stick, the form to be sown, scatter the seed thinly in the scratch thus made, and cover lightly by drawing a little earth over it with the hand. Poppies, Bartonias and some others should be sown where they are to flower, but most plants will bear transplanting and do all the better for it. Single flowers should not be tolerated where double varieties of the same kind are grown, as they will mix, and the seeds from them will be inferior. The old favorites, like Balsams, Asters, and many others will always be popular. They have been very much

improved within a few years; and only the finer kinds should be cultivated. The number of annuals is so large, and individual tastes differ so much in making a selection, that we only call attention to a few of those of decided merit, but which, though well known by amateurs, are not generally distributed throughout the country. We give engravings of a few of the newer sorts which have been tested. Each year a number of varieties are introduced with glowing descriptions of their beauty, and are often found, on trial, to be inferior to our old sorts. Having expended much money in trying novelties, we would advise our friends of moderate means to sow only those annuals which have been tested and found worthy of culture.

Whitlavia grandiflora.—This is a native of California; grows from 12 to 18 inches high, and bears a profusion of blue, bell-shaped flowers. It does best in a poor soil and is perfectly hardy.

Clintonia pulchella.—A beautiful little tender annual, suitable for vases or hanging baskets; flowers blue, yellow, and white. The seeds are very small and should be very lightly covered. We give the name *Clintonia*, because that is the one by which it is known among seedsmen and florists. The proper name is *Downingia*, in memory of the late A. J. Downing. The name *Clintonia* belongs to one of our native plants.

Clarkias.—These are half hardy California annuals. Several species and varieties are in

Fig. 2.—CLARKIA PULCHELLA—DOUBLE.

cultivation as *C. marginalis*, *pulchella*, *elegans*, etc. The double *C. pulchella* (fig. 2) is a rich rose color and very pretty. They all do well in a poor soil.

Rhodanthe Manglesii.—This has been for some time in cultivation. It is tender; from 12 to 18

inches high, with beautiful star shaped flowers, of a pure rose color. The flowers, being upon a delicate stem, droop so as only to show the under side, which is of a silvery gray. It belongs to a group, called "everlasting flowers." If taken off when they first open, they will re-

Fig. 3.—CALLIRHOE PEDATA.

tain their beauty for several years. They are desirable for winter bouquets. A new variety, *R. maculata* was introduced last year; it is larger than *R. Manglesii* and has a dark spot at the base of the ray florets. Both require a rich soil.

Acroclinium roseum.—Another "everlasting flower," and every way desirable. There are three varieties; white, rose, and deep rose. The plant is tender, and should have rich soil.

Callirhoe pedata (fig. 3).—One of the mallow family, from Texas, one of the best of the new annuals. Flowers, rich purple with a white centre. In good soil, and with proper cultivation, it will grow three feet high and flower for a long time.

Centranthus macrospilon.—This is one of the annuals which look well in masses; grows about a foot high and is covered with clusters of pink flowers. A white flowered variety is very pretty. The two may be massed together.

Salpiglossis.—The different varieties of this should be in every collection. They should be started early and then planted in a rich spot.

Schizanthus pinnatus, *Priestii*, and others are half hardy and of great beauty. They grow about 18 inches high, and are covered with delicate white, rose, violet, and other colored flowers.

Zinnia elegans—double flowered (fig. 1).—If limited to but one annual, we should grow the double *Zinnia*. Next to the Dahlia it is the showiest plant in the garden. We have seen them quite as double and almost as large as the Dahlia. To keep them in perfection none but plants having double flowers should be allowed to grow. Select the best of such for seed. We have often purchased seed from the most reliable dealers, warranted double, and not one plant out of a dozen would grow double. Our experience is, that seeds from double flowers will produce single plants, unless the soil be very good, and the weather favorable. Seed sown one year, grew mostly single, coarse flowers; the next year some of the same lot of seed, on

better soil, and with more favorable weather, turned out nearly all double flowers.

Ipomoea limbata.—This is a great improvement on the old Morning Glory, with flowers twice as large, of a deep blue color with a white border. *I. coccinea* has bright scarlet, and *I. grandiflora* white flowers. The seeds germinate freely if soaked in luke-warm water. The seeds of the above may be obtained at the principal seed stores. A number of them have been given out in our seed distribution. We have no seed store, and only keep on sale a few appropriate books,

Fig. 4.—RHODANTHE MACULATA. (See preceding page.)

it being our aim to keep clear of all *pecuniary* interest in any article, that we may always speak and write with the utmost independence.

THE HOUSEHOLD.

Variety in Food Necessary.

We have from a subscriber, a very long communication, which he insists upon having published in the *Agriculturist*. He argues with more words than wisdom, that a plain, simple vegetable diet confined to one or two varieties of food, is the best, and the only natural one; and among other things, he says in illustration, that disease is far less prevalent in those parts of Ireland where potatoes are the chief food, and in India, where rice is the staple diet. First, let us say, that we can not accede to his demand, that his peculiar and personal views shall occupy half a dozen columns; the editors alone are responsible for the matter used, and their judgment must direct what articles will best meet the wants of the readers taken as a whole. The threat in this and other cases, that a subscription or two will be stopped, if their individual wants can not be attended to, is a small matter, and not involving the loss of four-pence ha'penny of profits any way.

On the subject of variety of food, a few thoughts may be useful. The human body is made up of different elements; its parts are continually wearing out, and food is required to replace the worn out portions. For example, we have the muscles or lean flesh, and upon the size and vigor of these muscles depends our ability to exert force. It is the contraction of the muscles which draws up the arm in lifting, or moves the legs in walking. The muscles are largely composed of what are called nitrogenous elements. There is a close resemblance in the composition of the muscles, and that

of cheese, the whites of eggs, or the gluten of wheat, etc. The lean flesh of animals, like beef steak for example, is of the same composition. It is certain therefore, that these and similar substances furnish the best nutriment or food material for supplying a man with muscles—making him strong. Without such food, he would soon become weaker than the rice eating natives of India, for they get some muscle making nutriment in the rice.

The human body is kept warm by a process very similar to heating a stove. In the stove we place wood, or other fuel containing a good deal of carbon (coal), and the condensation of the oxygen of the air in uniting with it, gives out heat that was before latent. We eat food, containing carbon; after being dissolved in the stomach a part of it goes into the blood; the blood goes to the lungs and there receives oxygen from the air which acts upon the food or carbon in the blood and produces the heat that keeps our bodies warm. If we did not eat carbonaceous food, the body would soon become cold and dead. But as a safeguard against a cessation of the internal fire, through lack of fuel, as when food chances to be lacking for a time, or when sickness prevents the digestion of food, some extra fuel is always kept on hand in the form of fat which is stored up in cells, in larger or smaller masses throughout the body. When long deprived of food, this fat is all consumed, literally burned away to keep the body warm. Fat meats, butter, oils, starchy substances, like potatoes, fine flour, etc., are mainly composed of carbon or coal, and these constitute the best materials for supplying this kind of food, that is for keeping the body warm. The bones, or frame work, of the body are composed largely of mineral substances, mainly phosphate of lime, and as the bones are constantly diminished by absorption, bone-making food must be consumed, or the structure will tumble down for want of a frame. The phosphate of lime abounds in wheat, in milk, and is found more or less abundant in nearly all of the substances used as food.

It is estimated that, on the average, the human system requires about seven times as much carbonaceous food to keep up its heat as of nitrogenous food to restore the wear of the muscles and tissues. The best food is that admixture which supplies the different elements in about the proportion required by the body. In colder weather, or when little physical exertion is made, the proportion of carbonaceous food required is relatively greater.

The combination required can be supplied wholly from vegetable substances. Wheat contains the different elements required by the muscles (in its gluten,) by the heating apparatus (in its starch and oil), and by the bones (in its phosphates). Rice and potatoes are mainly carbonaceous, heat producing, and require cabbage, milk, or other nitrogenous material for the muscles. The rice eaters of India are deficient in strength and activity. Children fed on rice, sago, tapioca, etc., require milk or meat. Eggs are mainly nitrogenous, and go well with fried pork (ham and eggs for example), which supplies the carbonaceous or heat producing elements. Beans and peas in like manner are appropriately eaten with fat pork, if not in such quantities as to overtax the digestion. Milk from fresh or nearly fresh cows, contains the different elements in about the required proportions; its casein (cheese) supplies nitrogen; its oil or butter supplies carbon; and its phosphates supply the bone elements.

A mixed diet, one containing all the elements needed for the different purposes required in the system, is the most natural, and most healthful. The best food is that containing the different elements in the needed proportions. The intelligent provider for the household, or rather for the table, will study the requirements of those who are to eat there, and adapt the food to their necessities by a proper variety, if she have a choice of materials.

As to whether it is desirable to confine ourselves wholly to a vegetable diet, there is this to be said: Vegetables are, as a rule, coarse compounds, requiring a considerable tax upon the digestive organs to reduce them to nutritious chyle in the stomach. A man living upon rice or potatoes with

plenty of cabbage would get the needed elements, but he must digest a large bulk of them. Another may get an equal amount of real nourishment by eating a small quantity of beef, eggs, or cheese, and a little oil, butter, or fat meat. The vegetable diet may do well for those having little to do but eat, digest, and sleep; active, energetic people, require concentrated animal food which supplies a great amount of nourishment at a little tax upon the digestive organs. Herbivorous animals have larger stomachs, and longer intestines, which extract a greater amount of nutriment from the coarser vegetable substances in passing through the body than can be done by the human organism.

A Good Churn Dash.

A subscriber, Dennis J. Bardwell, Winnebago Co., Wis., sends to the *Agriculturist*, the sketch of a churn dash, shown above, which he pronounces a cure for cream that will not give up its butter. It is simply two plates of wood, cut to the form shown, and fastened upon the upright handle, one at the bottom, the other three inches above it. The projections of one are opposite the indentations of the other. The dash is worked up and down in the old-fashioned way. This form is well calculated to cause a great commotion in the cream, which is continually forced against the edges of the projecting parts, and thus the butter globules are quickly broken. Mr. B. says from 6 to 10 minutes will now usually suffice to churn, where 20 to 60 minutes were formerly required with the dash in common use. The apparatus looks effective, and is easily tried.

The Employments of Women.

This subject is becoming increasingly important, as the continuance of the war on so vast a scale is tending to the further inequality of the sexes. Tens of thousands of females will be deprived of the aid of those to whom in ordinary times they would look for support, and they will necessarily be thrown upon their own resources. There are many kinds of labor and business now performed by men which might be equally well if not better done by women. In the *American Agriculturist* for March, we referred to a new Work by Miss Virginia Penny, in which is given the results of extensive recent research and inquiry upon the subject of female employment. The information is not quite so definite as would be desirable, yet there are thousands of items regarding the different kinds of labor, the prices paid, the success of females in some kinds of labor, etc., which are interesting, and we think the circulation of the work will tend to awaken further inquiry. It will doubtless indicate to many females some new employment to which they may turn their attention. (Those desiring the book may obtain it through our book list, when not otherwise more conveniently accessible. See the advertised list on a subsequent page.)

From this book we learn that, according to the last census report (1860), there were only 285,000 females employed in the various branches of manufacture throughout the United States. This is a much smaller number than we should have expected to find. Miss Penny enumerates and gives some details concerning over 500 different employments

in which females are or might be engaged, and a large proportion of these come under the head of manufactures.

In 1848, when Paris contained less than one million inhabitants, there were employed in only thirteen branches of industrial labor, 112,891 women, 7,851 girls between the ages of 12 and 16, and 869 under 12. Over twelve hundred other occupations of females were officially reported. The following selections are interesting.

Occupation.	Men employed.	Women employed.
Boot and Shoe Makers.....	13,553	6,713
Makers of Shoes to Order.....	7,511	1,555
Chasers and Engravers.....	330	21
Gilders and Silverers of Ware.....	442	163
Gilders of Wood and Paper.....	878	329
Makers of Military Equipments.....	1,649	2,254
Dealers in Furs.....	232	399
Makers of Kid and Cloth Gloves.....	1,064	1,076
Copper-Plate Engravers.....	266	62
Dealers in Linen Drapery.....	80	8,974
Manufacturers of Linen Drapery.....	80	2,331
Embroiderers of Furniture.....	473	941
Makers of Painters' Pencils and Brushes.....	114	129
Feather Dressers.....	78	533
Polishers and Burnishers of Gold.....	23	284
Tailors.....	17,726	13,716
Makers of Hat Morocco.....	293	356

The number of shop-keepers is not stated, the very thing we would like most to know, for during our visit last season we were specially interested in observing that both in London and Paris, but especially in Paris, the clerks or sellers in the retail establishments of almost all kinds were chiefly females. A majority of the ticket sellers at the railway stations were also females; while in those saloons or eating and drinking houses where the lower classes of men were most apt to be found, men were employed as waiters, etc. An exception to this was seen in some of the beer shops of London, where well dressed and apparently modest females behind the counters were compelled to listen to the profanity and low language of drunkards and vile men. Throughout France the police regulations are so strict that females very appropriately occupy the railway ticket stations, and other public offices. We think that in this country there are tens of thousands of situations in our retail stores, and in ticket offices, etc., which might be occupied by women. The habitual respect and courtesy here shown to women, would protect them from insult, and perhaps a well dressed, well behaved woman in many of our public offices would tend to make them less the resort of boisterous men. In this city there are certainly many thousands of men becoming effeminated by standing behind the counters dabbled in tapes, silks, and ribbons, who should give place to women, and themselves go forth to the sterner employments of man.

Another thought in this connection. There is an increasing demand for fruits and flowers, and may not these be more cultivated by females than they now are? Near our cities and large villages especially, many a widow with her dependent family, might, from an acre or two of grapes and other small fruits, derive a livelihood. The training of the trees and vines, their protection from insects, etc., are appropriate work for women and children, far more healthful and invigorating, than the now "everlasting stitch, stitch, stitch," which is thought to be about the only work a dependent woman may do for others, with credit to herself.

For the American Agriculturist.

Hints on House Cleaning.

The first place to attack is the cellar. It should not be neglected, because "nobody will see it." Neatness is desirable for its own sake. A well kept cellar is essential for health as well as comfort. No person of common sense would think of building a dwelling over a swamp hole: yet many are living over cellars which are little better. The dampness from want of ventilation in that department, and the effluvia arising from decaying vegetables, are undoubtedly frequent causes of fever and ague. It is preferable to have the main portion of potatoes, roots, cabbages, etc., stored in a cellar apart from the house, and to bring in a supply occasionally as needed. But let everything be thoroughly over-

hauled now, and all decomposing substances removed. Clear out every unoccupied box and barrel. Rout the spiders that have curtailed the windows and festooned the beams overhead. Stop all rat holes, and repair places which they have gnawed. Caustic potash, or chloride of lime, scattered near their haunts, are said to be efficacious in driving them away. A good floor of cement is an excellent preventive of their sapping and mining. After a complete clearing out, give the walls and ceiling a good coat or two of whitewash, and when all things are "set to rights," it will be a pleasure to enter what is usually the most repulsive part of the domicile. The garret will next claim attention. Not a little dust will be found quietly resting there, having taken refuge from continued assaults with the broom in the lower rooms. Before disturbing it, pack away all extra bed clothing, woolen garments, and other apparel not needed for present wear. Tight trunks or boxes will keep them safe from moths, if they be occasionally taken out and thoroughly beaten. Do not suffer an accumulation of rubbish in the garret. If an article is useless, it will not pay to store it; sell it, give it away, or burn it.

Before commencing with the other rooms, go through the pantries and closets. Clothes closets should not be neglected. Moths seek dusty, lousy corners for breeding. Sweep and whitewash the walls, scrub the wood-work, and stop all cracks with mortar or putty. Rooms should be gone through with in order, commencing at the upper stories. There is no need to let even the good man of the house know that this operation is going on. Undertake no more at a time than can be well finished in one day, and the grand domestic revolution witnessed every Spring in some households may be avoided.

AN OLD HOUSEKEEPER.

Washing Cotton Comforters.

"Economist" writes to the *Agriculturist*, that comforters can be made so that the cotton may be easily removed before washing. Her method is to place a layer of cotton between the calico, and tie it at points about six inches apart with coarse knitting cotton doubled. The needle is run through the whole thickness of calico and cotton, then returned, and the thread fastened with a knot. After the cotton is all properly secured, the edges of the calico are sewed together with a running stitch. When soiled, the threads are easily drawn from the edges, the ties are cut, and the cloth is removed and washed, leaving the cotton in a continuous sheet, ready to be replaced when the calico is cleansed. She says this can be done in less time than by washing the whole together, and the cotton will remain lighter and more comfortable, than it could be made by whipping after washing.

Mixed Cotton and Woolen Stockings.

A HINT TO MANUFACTURERS.

It is rather surprising that the improvement upon woolen stockings mentioned in the April *Agriculturist*, (page 118), should not have been adopted by manufacturers in this country. A valued correspondent "A" writes on this subject: "I found such stockings very common in Denmark and Russia thirty-seven years ago, and presume they are common all over the north of Europe; and probably from time immemorial have been thus knit, or with linen and woolen thread as you recommend, now cotton is so dear.

"Pure woolen stockings, I have given up wearing for many years, for I cut holes through the heels and toes of the strongest in three or four days—they doing me very little service. As I cannot find in our country the mixed woolen and cotton, I wear in the Winter thick, coarse cotton, and find these answer well, though I would prefer woolen if they did me any kind of service. I used to have a piece of stout cotton cloth sewed over the heel of my woolen stockings; but there were two objections to this; it made the stocking too thick and bungling at the heel, and the cotton cloth would not shrink

evenly with the woolen stocking, which thus caused wrinkles very uncomfortable to the heel."

To Prevent Stammering.

J. T. Hassett, Summit Co., O., writes to the *Agriculturist*. "When children see any thing remarkable (in their view), they are always in a great hurry to tell of it, and often the words crowd to the tongue faster than they fall from it, which induces stammering. On such occasions, the parent should instantly hush the child, until its excitement is over, and then give it the privilege to make the relation calmly." This is a good suggestion. It is known that an inveterate stammerer can be cured by practising some method which requires him to speak deliberately and in measured time. Some "Professors" who cure stammerers, require their pupils to heat time with the finger at each word, the same as in singing, and in this way the habit of control over the organs of speech is acquired. But prevention is always better than cure, and a little care at the first will entirely break up the tendency to stammer, which children often have.

"Hulling" Beans before Cooking.

MR. EDITOR: In response to your suggestion in the *American Agriculturist* last month, in reference to the very nutritious quality of beans, and their indigestibility unless the skins are broken so as to allow the gastric juice to act upon the inner portion, I send you my wife's mode of cooking them. I will premise by saying that for many years we have raised for our own cooking a small, bright, white pole-bean, planted with corn. The corn stalks support the vines, and do not appear to be in the least injured by them.—Before cooking the beans, they are hulled with lye from wood ashes, just as we prepare corn for what is called "lye hominy." There need not be the least taste of the lye left upon either beans or corn. Beans thus prepared speedily cook very tender, and make a wholesome and delicious dish, either as soup or mashed.

G. M.

Hancock County, Ind., March, 1863.

Hints on Cooking.

How to Cook Asparagus.—Cut the stalks when 6 to 12 inches high, and wash if needed. Some break the stems into short pieces, and others tie them whole in little bundles, a few stalks in each. They are then boiled in water slightly salted, for 25 to 30 minutes, and dipped out and drained. Lay toast in the bottom of a dish, and spread the asparagus over it. Pour over the whole a full supply of drawn butter, or what is better, gravy made of milk and flour—cream instead of milk makes it still richer. Add salt enough to season it. The good quality of the dish will much depend upon the skill exercised in making the gravy. If eaten in large quantities, asparagus is diuretic, though producing no serious injury. In moderate quantity it is not only palatable and moderately nutritious, but believed to be healthful.

Cheap Vegetable Soup.—Contributed to the *Agriculturist* by M. H. B. France, Susquehanna Co., Pa. Peel and slice a quart bowl of potatoes with two or three onions, and boil tender. Stir three tablespoonfuls of flour into cold water and add to the potatoes, with butter the size of an egg. Pour in water sufficient for four quarts of soup and season with pepper and salt to taste. Add a pint of dry bread or biscuit, boil a few moments and serve.

Mrs. Bunker's Soup.—A young housekeeper requests that Mrs. Tim Bunker will please communicate, for the benefit of the inexperienced, how to make that soup which her husband writes about with so much gusto, on page 87 (March No.).

A Dish for Hard Times.—M. A. Johnson, Grasshopper Falls, Kansas, sends to the *Agriculturist* the following directions for cooking a

dish, which she says was found economical during the long drouth in that State a few years since. "Cut two ounces of lean bacon, or a red herring, in pieces, put it into a pot, with three onions, a few pepper corns, and a small bundle of thyme and parsley, and three pints of water; let it boil three quarters of an hour. Then add to it one pound of clean picked whole rice, and let it boil just three minutes (no longer). Take the pot from the fire, and let it stand by the side of it, and the rice will swell, and take up all the water, and become quite soft. If properly done, it will weigh nearly five pounds, and will completely dine five men. If the rice be not sufficiently tender, a little more water may be added as it stands by the fire. This is a cheap and excellent dish."

Corn Bread without Milk.—Contributed to the *Agriculturist* by "Aunt Prudence," Tuolumne Co., Cal. On $\frac{3}{4}$ pt. of corn meal, pour $1\frac{1}{2}$ pint boiling water, to which add two heaping teaspoonfuls cream tartar, one of salt, and $\frac{1}{2}$ cup of molasses and let it stand all night. In the morning add $1\frac{1}{2}$ pt. of flour before it is sifted, and one heaping teaspoonful saleratus, well dissolved in $\frac{1}{2}$ pt. of cold water. Turn this into a tin pail thoroughly greased, and place the pail immediately in boiling water, and continue the boiling two hours. The cover of the pot should be wrapped in a clean cloth to absorb the moisture, which would otherwise drop from the cover into the pail and spoil a portion of the bread.

Transparent Pies.—Contributed to the *American Agriculturist*, by A. Thompson, Pendleton Co., Ky. Take 3 eggs, 2 tablespoonfuls of sugar, 1 teacupful of rich cream, 3 tablespoonfuls of jelly, 1 of butter, flavor with essence of lemon. The fairer the jelly the better, as it makes a nicer looking pie than dark jelly; either makes a delicious article. The above ingredients are enough for two pies. [From the absence of explicit directions, we suppose the materials are to be mixed, enclosed in crust, and baked in the ordinary way.—Ed.]

Hint on Boiling Potatoes.—"Aunt Prudence," writes to the *Agriculturist* that old and very poor potatoes are greatly improved by paring and soaking them in cold water for several hours previous to boiling. Good potatoes should be cooked without peeling.

Queen Victoria Pudding.—Contributed to the *American Agriculturist*, by M. Crane, Wis. Take one cupful each of flour, sugar, grated apples, grated carrots, finely chopped suet, and dried currants; season with one teaspoonful of salt, a little nutmeg and essence of lemon. Mix all well together without water, and tie it in a wet cloth. Place it in boiling water and cook two hours, or longer if the pudding be very large.

Milk Pudding.—Contributed to the *Agriculturist* by "C. B. D." Add to one quart of boiling milk, one teacupful of flour wet to the consistence of cream; when well cooked, mold in cups, turn out when cold, and dress with cream, sugar and nutmeg.

Fruit Cake.—Contributed to the *Agriculturist* by Mrs. C. Moore, Washtenaw Co., Mich. Mix 2 beaten eggs, 2 cups of sugar, 4 of flour, 1 of sour cream, 1 of butter, 1 tablespoonful cinnamon, 1 teaspoonful cloves, 1 of soda, 1 pound raisins chopped fine. Bake in a slow oven.—*icing for the same.* Beat the whites of two eggs to a froth, add $\frac{1}{2}$ pound of powdered white sugar, beat from 8 to 10 minutes, and apply when the cake is nearly cold.

Apple Fritters.—Contributed to the *American Agriculturist* by James Bricker, Indiana Co., Pa. Take any large sized apples, except sweet, pare them and cut them into circular pieces about one-fourth of an inch in thickness, at the same time taking out the cores with a sharp pointed knife. Make some batter of wheat flour as for common griddle cakes, drop the sliced apples into it, have ready a deep griddle or spider into which put about half a pint of lard. When it is hot, with a large spoon drop the apples into it; to be eaten while warm.

BOYS & GIRLS' COLUMNS.

Judge not from Appearances.

A few years since a party of ten or twelve clergymen went on an excursion on South Bay, Long Island. They had been cooped up in the city during the year, and wisely thought a week or two of recreation would prepare them to work with more vigor. They were dressed for the occasion with coarse clothing, thick boots and straw hats. They hired a sloop, and enjoyed themselves highly for a week, sailing up and down the bay. When Saturday night came, the sloop was anchored near a small village. In some way, a few of the inhabitants learned who they were, and the next morning a committee invited each of them to preach in one of the neighboring churches, which they accordingly did, to the great gratification of the villagers. On Monday, one of the number who was cook for the company, went ashore to buy some milk and eggs for breakfast. He stopped at a farm house, and stated his errand. "I've no eggs nor milk to sell," said the lady of the house. She spoke quite short, and with a scowl that seemed to say, "I don't want to deal with a suspicious looking man." The coarse coat, somewhat blackened by cooking, the tattered straw hat, and sunburnt face certainly were not prepossessing. After a little parleying she asked "Who are you in that boat?" "We are a good set of fellows, having a little fun," was the reply. "Humph, I should think so," said the lady. "Have you got any run on board?" added she spitefully. "Why madam, we are a company of ministers." "I guess you'll make me believe that" was the answer. "I believe you heard me preach yesterday," quietly remarked the gentleman. "Why, is that you?" exclaimed the woman throwing up both hands. "You shall have all the eggs, and all the milk, and any thing else you want." And after that there was nothing lacking in her hospitality. The clergyman gave her a gentle hint that clothing was not always a safe standard by which to judge of a man, and left her, greatly amused with the incident.

A Faithful Dog.

A tanner had a large mastiff to guard his premises from thieves. The foreman of the yard regularly fed the dog, and the two were on the best terms. The owner suspected the foreman of dishonesty, and discharged him. In this he was probably not mistaken, for a few weeks after the man determined to steal a load of hides during the night. He knew the premises perfectly, and felt sure his old friend the dog, would offer no resistance. He accordingly drove a cart near the fence, climbed over, and threw the hides, one by one out of the enclosure. The dog appeared pleased to see him, and did not offer to prevent his operations. When the man was ready to go, instead of unbolting the gate and passing out, he started to go as he had entered, climbing the fence, so as to leave no clue by which he might be detected. This unusual proceeding aroused the dog's suspicions, if such a term may be applied to an animal's ideas. He at once sprang upon the thief, seized him by the leg, and held him until the owner came to his assistance and secured the culprit.

Curious Sentence.—Translation.

Prof. E. North, of Hamilton College, N. Y., contributes the following concerning the curious Latin sentence, "*Sator arepo tenet opera rotas*," which was published in the *Agriculturist* on page 57, (Feb. No.) "This double palindrome (word or sentence reading backward and forward the same), is one of the most curious results ever brought about by the use of words. Notice that you may read four ways, and the sentence is the same. In translating put a colon after *arepo*. "As a planter I move slowly: industry checks the wheels."—This is a clumsy paraphrase of the familiar proverb, *festina lente*, "make haste slowly." The sentence is itself a good example of what may be accomplished by making haste slowly. Who can tell us the author of this scholastic curiosity?"

The Game of Matching Pairs.

Not infrequently when a company meet to spend an evening, it takes considerable time to get them mingled together. We have seen the gentlemen collect in one corner and the ladies in another, and not more than half enjoy themselves until some one of sufficient tact had distributed them more naturally. A correspondent of the *Agriculturist*, "Jim Hop Along," having been thus situated, after some study, has hit on the following game which will serve admirably to 'break the ice,' and produce some merriment. Cards or bits of paper are numbered from one upward to correspond with the number of gentlemen present, and another set of smaller ones are similarly prepared for the ladies. The two sets are first shuffled separately, and one given to each person, who must keep his or her number secret. Then a gentleman starts to seek his fortune. Approaching any lady he may

fancy, he bows and presents his card. Should the number on her card correspond with his, he salutes her and takes a seat by her side, and the next person on the right proceeds to make a choice. But if the first gentleman be unfortunate, the lady returns his card, gives him her seat, and starts to seek her own fortune, as he had previously done. The company soon become interested in the game: there is no little fun over some of the pairs thus brought together. After all are matched, if desired, the numbers may be shuffled again, and another trial made."

New Puzzles to be Answered.

No. 37. Illustrated Rebus.—A poetical quotation.

No. 38. Problem by J. W. Robbins, Tioga Co., N. Y. How can fifteen sheep be enclosed in four yards, so as to have an odd number and a different one in each yard?

No. 39. Arithmetical Problem.—Three men, A, B, & C, dug a ditch 100 rods long for \$100. The ditch being deeper at one end than the other, A, took the deepest part and got 20 cents per rod more than B, who took the middle part; and C, took the shallowest and received 20 cents per rod less than B. Each man received $\frac{1}{3}$; how many rods did each man dig?

Answers to Puzzles and Problems in April No. (page 121).—No. 35. Illustrated Rebus.—"Doe tont hers as theys hood dot ou." or Do to others as they should do to you. No. 36. Problem.—Answer: The clocks will show the same hour at 12 o'clock on April 15.

The following have sent in correct answers to recent puzzles and questions; the numbers indicate the problems answered by each: Annie J. Hooper, 29; H. A. Collins, 31, 32; John R. Wilkinson, 30; W. Nellis, 32; John Lee, 33; Nathan Tyler, 31, 32, 33; James D. McGiffert, 31, 33; Howard, 33, 34; Thomas D. Smedley, 33; Geo. C. Comstock, 31, 32; Noah S. Barnum, 31, 32; A little girl, 32; Israel C. Rinehart, 31, 33, 34; Calvin B. Bradley, 30; David Sheaffer, 31, 32, 33, 34; Joseph Kerschier, 33; Purinton Maryot, 31, 32, 33, 34; Joseph Kirk, 31, 32; Samuel F. Lazaar, 33, 34; Fred. Boys' and Girls' Garden—No. 2.

The articles under this head have an important end in view. We expect, by gradual, easy steps, to teach those who read them, some important and useful lessons, to lead them to become closer observers of the wonderful things in the natural world, and thus add greatly to the interest of their future lives. Some of you may become skillful botanists before you know it. We hope every

Fig. 1.

one will follow our suggestion, and sow the seed as we recommended, and apply the description to the plants themselves. Study these articles enough to become familiar with the few apparently hard names we introduce. Please learn the A B C's, and you will soon become interested readers. Read the review ending this chapter.—In the last number, we told our young friends what seeds to plant, and probably many have them already in the ground. There is no need to be in a hurry, for any time in May will be early enough to sow them. The Sweet Peas and Morning Glories should be put where they can have strings or brush to run upon, and the Melon should have room enough to spread itself on the ground. The seeds being in the ground, we must now wait patiently for the plants to show themselves. After a while—which will be longer or shorter, according to the weather, and the depth to which the seeds were covered—the ground will break and the little plants will push through, and all but the Peas and Oats will spread out two little leaves to the light and air. If there are plenty of plants of the Melon, you can afford to take up one or more carefully, and you will find it will look as in fig. 1. It has root, stem, and leaves, and though very small, it has all that a plant needs to enable it to grow. Wonderful indeed have been the changes which have been going on in the dark ground; a little dry lifeless looking seed was put in the earth, and now we have a living plant. Before we watch the growth any further, let us see what has been going on out of our sight, and where this plant came from. Take a piece of cloth and wet it and fold it a few times so that it will lay on a plate or saucer; put a few of the Melon seeds between the folds of the cloth, cover with another plate or saucer, and keep it in a warm room. We have now the seeds in very much the same condition as they are in the soil, they have warmth, moisture and air, and all these are necessary in order that the seed may grow. The seed soon begins to swell and in a day or two, the skin or seed coat will break open, and a little point of stem will be seen pushing itself out of the crack. This stem will go on increasing until it gets to be several times longer than the seed, (fig. 2.) The seed-coat will be pushed off and the two seed-leaves will show themselves. If the cloth has been kept moist, we shall get in this way a little plant just like the one which grew in the ground, except that it will have no roots, (fig. 3.) It will be noticed that this plant all came out of the seed, for we have given it nothing but water. Now, what was in that seed at the beginning? We must pick it open and find out. Let us take a melon seed and soak it until it becomes a little softened, and then pick its coat off carefully. We shall find inside of it two little leaves, rather thick and plump, joined together by a very short little stem, (fig. 4.) A little plant then is really packed away in the seed, only differing from the plant in fig. 3, in the length of the stem. This is the embryo.

Fig. 3.

rather thick and plump, joined together by a very short little stem, (fig. 4.) A little plant then is really packed away in the seed, only differing from the plant in fig. 3, in the length of the stem. This is the embryo.

Now as quite a growth takes place when it is not in the ground it is plain that all the material for this growth must have been provided beforehand in the seed. This is really the case. The two seed leaves are thick from being filled with food which is to enable the plant to make

Fig. 5.

its first growth—which is to push out the little stem. If the seed is in the ground this stem lengthens; the lower end pushes downwards, and the other end works its way to the surface. The plant can make its growth, thus far, from its store of food, but roots soon start from the lower end of the stem, by means of which it can draw nourishment from the soil. Now we have described the plant thus far without the help of any unusual words, but as there are terms which are used to express the parts, we may as well know what they are. The little stem is called the *radicle*, and the seed-leaves are called *cotyledons*. The cotyledons or seed-leaves are unlike in shape to those which will follow them, but they are nevertheless leaves. In many plants they fall away after other leaves appear, but in the melon they will grow large and remain for a long time. We find that the leaf in this case is made to do two things; while it is in the seed it serves to hold food for the first growth of the plant, and afterward it comes to the light and air, and acts like other leaves in helping the plant to grow. Our little Melon plant has at first only a pair of leaves, but soon a little bud will appear between them which contains the leaves that are to follow. This bud is called the *plumule*, (fig. 7); it is to be found ready formed in some seeds, and can be easily seen in the bean.—Let us now see how some of the other seeds are getting on. The Tomatoes will be likely to be rather slow in coming up, but after a while their long seed-leaves will make their appearance. The Peas will seem quite unlike the rest in their way of growing, and you will watch in vain for the seed-leaves. They are there hidden underground, and if one is dug up, the two cotyledons will be found, but so filled up with food for the young plants, that they will never be able to serve as leaves above ground, so they remain below and give up their nourishment to the plumule which grows rapidly, (fig. 5.) The right hand figure is the pea, with its skin off, showing the radicle; and the left hand figure shows the radicle and the plumule growing. The Four O'clock and Morning Glory will show two seed-leaves when they come up, which will look more like leaves than those of the Flax and Melon; they are very thin—too thin to have held much food for the young plant; still the food is stored up in the seed, but not in the embryo itself. Place some of the Four O'clock seeds in a wet cloth until they begin to sprout. Then break them open and carefully remove the embryo plant—it will be found carefully rolled up and coiled around a little ball of what appears like flour. A seed cut in two will look like fig. 6—where the dotted part represents the floury portion with the embryo coiled around it. Now this little mass of flour is put here for just the same purpose that the matter which thickens up the seed-leaves of the melon is put in them—for food to enable the little plant to grow until it makes roots, and can get along without this help.—Here the same thing is done in two different ways. In the melon the food is placed in the embryo, and in the Four O'clock it is outside of it. When the food is not in

Fig. 6.

the embryo, it is called *albumen*—and we have already seen that some seeds have albumen and some do not. The Flax, Melon and Pea, have no albumen, while the Four O'clock, Morning Glory, Tomato and Oat have. The albumen of the Morning Glory is not floury like that of the Four O'clock, but when wet appears like jelly. We have not space to show how the embryo is arranged in different seeds, but that can be learned by and by. When the oats come up they will not show seed-leaves, nor will you be able to find them by digging down as in the case of the pea. The seed of the oat is small, and its embryo much smaller, and it requires a good magnifier and some skill to be able to see it. So you will have to rely upon our engraving to see how the embryo Oat (fig. 8) looks.—Fig. 8 shows the embryo at the lower part of the albumen, and fig. 9 shows the embryo separate; instead of two seed-leaves, there is but one, and this is coiled around, showing the plumule above, and the radicle below. This one seed-leaf never comes to the surface. All the other plants we have mentioned have two seed-leaves while the oat has but one. This difference does not appear very important to you, perhaps, but it is a distinguishing character of two very distinct classes of plants—differences which are seen in the embryo, and as the plant grows are found in all its other parts. Now, as the distinction between those which have two seed-leaves is an important one, perhaps you will go to the trouble of learning the names by which they are called in the books. Those with one seed-leaf, or cotyledon are called *mono-cotyledonous* plants. *Mono* meaning one. Those with two cotyledons are *di-cotyledonous*. *Di* means two. You must not be discouraged at these names, for we shall not have occasion to use many such hard ones.—The plants being fairly up, the plumule or little bud soon appears; it is soon lifted above the seed-leaves, a leaf or two leaves open—another bud appears above these and so the plant goes on to increase in length. Down in the soil the roots are increasing in size and number to keep pace with the growth above ground.—But we have given you quite enough to observe in the little garden for the present. When you have seen how the seeds start there, it will be interesting to watch other seeds which the older people have planted, and see that they, though differing in appearance from yours, are all growing upon the same general plan.

Review.—1. Don't neglect to start some of the seeds. The above pictures are exact copies of growing seeds, started in a folded towel, and kept moist and warm between two plates, a few days in the *Agriculturist* office.

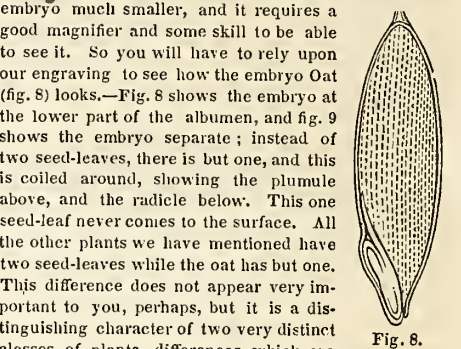

Fig. 8.

Fig. 9.

2.—What is the *embryo*?
3.—What is the *radicle*?
4.—What are *cotyledons*?
5.—What is a *plumule*?
6.—Where do cotyledons of peas grow?
7.—What is the *albumen*?
8.—Which of our seven chosen plants feed on albumen?
9.—How do the others feed?
10.—How does the albumen of the Morning Glory differ from that of the Four O'clock?
11.—Have oats any seed leaves or cotyledons?
12.—What are *mono-cotyledonous* plants?
13.—What are *di-cotyledonous* plants?

A Farmer Without Arms.

W. M. Beauchamp, Onondaga Co., N. Y., sends to the *American Agriculturist* an interesting account of a farmer he formerly knew, who was born without arms. "Instead of appealing to the charitable for support, he commenced early to help himself. His first property was a hen and chickens, next a pet lamb, and afterward a shaggy colt. He took good care of these, and increased his stock, a little at a time, until he became a prosperous farmer. Having no hands he learned to use his toes, which were longer than common. His legs were also very flexible, and by practice he was enabled to readily perform most operations with ease. He put on and took off his own clothing, shaved, and fed himself, milked his own cows, and took part in most labors of the farm. He was a terror to evil doers, whom he could punish with severity. He was powerfully built, and possessed of great strength in the head and shoulders. He would butt like a ram; or seize an offending urchin with his teeth, and shake him with bull-dog tenacity. He died at the age of seventy, leaving a large family—having been married three times."

A BEAUTIFUL REPLY.—A lady in Switzerland, addressing a peasant who was working in his garden very early in the season, said, "I fear the plants which have come forward so rapidly, will yet all be destroyed by frosts." "God has been our Father a great while," was the reply.

Question About Robins.

We had always supposed that robins returned regularly every Spring to build their nests in the neighborhood they had frequented the previous year. A recent English writer thinks differently, and even believes the parent birds may be killed off by the young ones when they have grown to mature robin-hood. He says: "This is a subject which has occupied my attention for several years; and, although I have not arrived at any satisfactory conclusion, my experience may not be uninteresting. I have for the last four years had one, if not two, tame robins, each year, but never more than one on the same part of the premises, and never the same bird for two years. One has located itself in the shrubbery, and the other in the garden or orchard. My proceedings have been as simple as possible. When I first observe a young robin, I throw it a bit of bread, calling at the same time, 'Tom! Tom! Tom!' I gradually diminish the distance to which I throw the bread, until in a very few days the robin will come at the call of 'Tom,' and, eventually, will feed from my hand as I sit on a garden seat. I am generally away for about five weeks at Christmas, but Tom is sure to be ready to greet me on my return. When pairing time comes, my *protege* introduces his or her mate, as the case may be, and then I have two visitors for a time. I know when they have hatched their brood, because then the birds fly away with their bread, instead of eating it on the spot. None of my pet birds have ever built within my own premises, but still they continue to come for their daily portions, until the young have left their nest. Then a change seems to come over them. The mate disappears altogether, but my own pet still comes to be fed, but is not so domesticated with me as before; and whenever a young robin makes its appearance, it seems furious at the sight of the old one; and, as the former acquires strength, it appears to quite terrify the parent bird, and before the Autumn sets in I lose my old companion, to go through the same phases with its successors. Two years ago, after the old robin had been absent for some weeks, I noticed it in the orchard—its own walk had been the shrubbery—and called as usual, 'Tom!' The bird came and took a bit of bread from the garden seat; but as it was making off to a distance to enjoy his repast, a young robin flew at it with violence, chased the bird out of bounds, and I saw it no more. This robin was conspicuous for a white feather in one wing, so that I could have detected it amongst many. From the above, I can only come to the conclusion that the old robins either die a natural or a violent death, or migrate to some other locality. If one robin has a peculiar haunt, a robin, but not, I am convinced, the same bird, will ever be found in the same place; but seldom, if ever, more than one."—It would be very interesting for our young friends to try and decide this question by observation. We think that our favorite bird must have been slandered by supposing him capable of parricide.

a strong light and the wall, or some other white, plain surface, and the shadow will give a fair representation of a highly wrought dandy. This design, with several others, was contributed to the *Agriculturist* by Letty Ermin.

The Agriculturist Grind-stone.

I say, mister Editor, will you please grind my axe?
Editor—Yes sir, with pleasure, if it be a good one.

Hi! hi! Look Here! You have ground the edge all off.
Editor—That's because it was not made of true stuff. It's fixed now so it won't hurt anybody. Whose turn next?

Notes on "Vineland Lands."

On our way home from Washington. March 5th, we stopped over a day at Philadelphia, and made a flying visit to "Vineland," not so called from any abundant native growth of the vine, we suppose, but rather because it is hoped the vine may be made to grow well there, or because the name itself is a euphonious one. The trains for the day only admitted of a stay of 2½ hours—too short a time to canvass the merits of a large tract of land, though we made the best possible use of the time, and walked or run several miles, and with the assistance of a man with a spade, and by the examination of cellars and wells being dug, and a few tilled plots, we gained some idea of the character of the soil. We purposely avoided interested parties, preferring to see the plot rather at random, than to be guided to any particularly favorable location. The tract lies about 35 miles directly south of Philadelphia, and appears to have lain idle for many years at least, and little of it has ever been tilled. The location seems to be a healthy one. The surface is rolling, rather more uneven than most of our Western prairies. It is covered with a shrubby oak underbrush, with here and there small pines, and the stumps show that from time to time a scattering growth of smallish oaks has been cut off. A railroad from Philadelphia, to be extended to Cape May, and already nearly opened there, brings Vineland within easy distance of Philadelphia. The tract is well laid out, and the title appears to be good, which cannot be said of all the new lands offered, in the vicinity of this city at least. The soil is sandy, too much so for profitable culture without free manuring. The surface is not so pure a sand, as some of the wild lands on Long Island, and so far as we examined it, the underlying gravel and pure sand strata do not come so near the surface. On this account, it will be less severely affected by drouth than those portions of Long Island where the gravel beds come so near the surface as to prevent moisture ascending from below by capillary attraction. (See *Agriculturist* for May, 1860.) Some who have been over more of the ground at Vineland, tell us that the pure sand does occasionally approach the surfaces, and even crop out at some points. We did not chance upon any such plots. Visitors prospecting at Vineland will be differently affected, according to the character of the country they

came from. Thus, some persons from the sandy regions of Southeastern Massachusetts, tell us the Vineland soil is very good; while those accustomed to the clay and loam lands of Upper Canada, Western New-York, Northern Ohio, and elsewhere, pronounce it quite too sandy for profitable culture. We found some at Vineland, especially mechanics, earning a livelihood from their trades as builders, etc., who talked very hopefully; we saw a few others, who are anxious to sell out.

It requires considerable outlay to clear off the underbrush, plow out or grub out the roots and stumps, fence, and build upon the land; we judge \$20 to \$30 per acre to get the soil into fair condition for cultivation, aside from buildings. Some estimates put it at \$3.50 per acre to cut and burn the brush; \$3.50 to \$4 per acre to run a heavy plow through it, leaving the large old stumps, or \$15 to \$17 per acre for "grubbing," without taking out the stumps, and then the harrowing, seeding is to be done; and the fencing as needed.

The soil must have manure to produce at all well. It is proposed to get it into clover and turn it under for manure. Time is required for this, and any one preparing to locate there must take into account the first cost of the land (\$15 to \$30 per acre, according to the location); the preparation of the surface; fencing, buildings, etc. It is evident that a poor man, or one with only about enough to buy the land, would starve while fitting up a productive farm, unless he depended upon laboring for others to support himself. We would not advise any one to think of going there unless he has some ready money to expend upon the land, and to live upon for a year or two at least. The mere fact that the first cost of the land is small, compared with other sections, is not the only thing to be taken into account. What it costs to get it into profitable use, is quite as important. Mechanics and tradesmen, earning their livelihood in Philadelphia, or elsewhere near at hand, might perhaps find it worth while to expend their surplus earnings in fitting up a homestead at "Vineland," though they must consider, whether fewer acres at a higher price may or may not be a more profitable investment. Those seeking farms may also consider whether the land at Vineland is cheaper in its present condition, than older farms in the vicinity, already fitted up, though held at a higher price per acre.

We have said thus much to give the best information we could with our limited observation, to a large number of inquiring readers. Mr. Landis, who has charge of the Vineland settlement, appears to be somewhat enterprising, and the laying out and beginning of the prospective village and town, indicate taste and public spirit on his part, though he, like all others, doubtless has an eye to the ultimate profit. If he can bring in a class of persons who can afford to work the land up to profitable tillage, it will be so much gain to that part of New-Jersey. We learn that several hundred purchases have been made, and the new buildings going up, and the "clearings" begun here and there, indicate a purpose to see what can be done. Hundreds of persons from all parts of the country have been at the expense of a journey thither to see for themselves, and the reports brought back by many who have made our office a stopping point in their journey, are very various. The main object of the present article is to give our distant readers some items for judging whether it is worth their while to be at the expense of a personal visit. A more extended examination, at a more favorable season for seeing the vegetation, may give us a better or poorer opinion of the Vineland enterprise. The wide notoriety given to it by advertising and otherwise, and the multitude of inquiries addressed to us, justify the attention and space we have given to the subject. We are only sorry that we are not able to speak more definitely and positively. If the Vineland enterprise proves successful, and good farms are there developed, the example will be very beneficial to other large tracts of similar soil, now lying mainly unused, all through Southern New-Jersey.

Our Exhibition Tables.

These have necessarily received less attention during our busy season, and during the Winter months there have of course, been greatly diminished contributions from the field, orchard, and gardens. Now, that the growing season has come on, we invite all who have objects of interest relating to the farm, garden and household, to place them upon our Tables where they may be freely seen by the multitudes who call at the office. During the year 1862 the number of callers on business and otherwise averaged over 300 a day, or nearly 100,000. The table will be re-arranged this month, and objects placed thereon will be seen and enjoyed by a great number of interested persons. The Fruit Growers' Meetings continue with unabated interest, and will doubtless continue throughout the year, on Thursdays of each week—at 1 o'clock P. M. for the present. It was proposed at first to have weekly prize exhibitions of fruits, etc., and a fund was raised for

A Shadow Picture.

This picture is not a very handsome one, to be sure, but if properly managed, it may produce some amusement. Copy it upon a piece of stiff paste-board, and then with a sharp knife cut out the unshaded parts. It can be done easily by laying a piece of thin paper over this engraving, and marking the outlines of the white parts. Then paste this smoothly upon the paste-board, and follow the lines with the knife. Leave the edges of the cut square and smooth. When finished, hold it between

that purpose; but after full discussion, it was decided that there was abundant public spirit to keep up the exhibition without the stimulus of prizes, while the awards of prizes would be constant sources of dissatisfaction and heart burning. Committees on articles exhibited will be appointed for each month, and receive and examine fruits, etc., and report them to the general meeting. It is desired that fruits, etc., be sent in at 11 to 11½ o'clock A. M. on Thursday of each week, when they will receive the attention of the standing committee. The Prize Strawberry Show in June, and the Pumpkin, Squash and Gourd Show in October, will be announced elsewhere. The following contributions to our Tables have been made since our last report:

FRUITS.—Apples: The Freeman, Harrison, Baldwin, Canfield (sweet), Poughkeepsie Russet, and R. L. Greening, from E. Williams, of West Bloomfield, N. J.; Peck's Pleasant, from A. G. Baldwin; Queen Seedling of King, from P. J. Ward, of Bloomfield, N. J.; Sweet apples and grafts for distribution, from Mr. Stewart, of Middle Island, Conn.; Canfield apples from Mrs. Wheeler, of N. J.; Northern Spy, from Mr. Parish; Iron apples, from G. M. Usher, of Port Richmond, S. I.; King of Tompkins Co., from E. C. Frost, Highland Nurseries, Schuyler Co., N. Y.; Seedling apples, from J. D. McCabe, of White Plains, N. Y.; Newtown Pippins, from W. S. Carpenter, of Rye, N. Y.; Newtown Pippins (fine) from P. Voorhees, of Nyack, N. Y.; Eng. Golden Russets, Hubbardston Nonsuch, Newtown Pippins, Baldwins, from J. L. Gougas, of Weston, Mass.; Variety for name, from N. R. Grants of Rockville, Conn.; Pears: Vicar of Winkfield, in Winter, from W. S. Carpenter, of Rye, N. Y.; Great California Pear (3 lbs. 7 oz.), from Dr. Bellows, of New-York City.

FLOWERS.—Camellias (fine collection), specimen of Hexacentris Mysorensis, from Wm. Chorlton, of Staten Island; Bouquet of flowers made of wood, from John Sievers, of Hackensack, N. J.; Chinese Pinks in bloom in March, 8 large pots from M. Olm, in charge of grounds of O. Judd, at Flushing, N. Y.; Strelitzia Regina, or Bird of Paradise (very fine specimen plant) from E. James, East Morrisania, N. Y.; Cranston New Seedling Petunias, ditto Heliotrope Chieftain, from Mr. Cranston, Hoboken, N. J.

VEGETABLES, SEEDS, ETC.—Garnet Chili Potatoes, from P. H. Foster, Babylon, L. I.; Large Turnips, from Wm. T. Peck, of N. Y. City, and L. F. Defiganieri, of Greensburg, N. Y.; West India Yam (14 lbs.), from Mr. Bitter, of N. Y. City; Mormon Cotton, from C. H. Howard, of Utah; Yankton Corn and Mandarin Corn, (said to be ready for table in 40 days after planting), from Judge Caton, of Ottawa, Ill.; Specimens of White Flint Corn, from Abram Brown, of Deer Park, L. I.; Dent Corn (very large), from A. Monfort, of New Utrecht, L. I.; Chicory, from Solon Robinson, of N. Y. Tribune; Cotton, (grown at Deaf and Dumb Institute, Washington Heights), from Mr. Morris; Fancy Gourds, from A. S. Quackenbush, N. Y.; Corn from Wm. M. Pierson, of Brooklyn, N. Y.; Corn for name, (yields upwards of 100 bushels shelled corn to the acre) from E. Bunderhill, of Yorktown, N. Y.; Corn for name, from N. R. Grant of Rockville Conn.

IMPLEMENTS.—Model of N. J. Corn Marker, from D. C. Voorhees, of Blawenburg, N. J.; Patent Hog Ring, from Daniel Brown, of Lawn Ridge, Ill.

MISCELLANEOUS.—Sorghum (excellent—improved method), from E. A. Van Meter, of Burlington, Iowa; Sorghum, (very fine, made on Cook's Evaporator), from Blymire, Bates & Day, of Mansfield, Ohio; Sorghum Sugar and Syrup (from Otaheitan cane), from H. B. Montrose, of Tremont, Ill.; Prepared fiber and cloth made partly of China Grass, from Wright & Whitman, of Boston, Mass.; Prepared Flax, from Mr. McFarlane, of N. J.; Cotton cloth (made from Illinois grown cotton), from Rev. J. A. Bent, of Hoytston, Ill.; Strawberry Wine (good), from L. M. Pease, of N. Y. Industrial School; Cherry Wine, and Clinton Grape Wine, from Oneida Community, Oneida, N. Y.; Currant Wine, from J. C. F. Rommel; Concord Grape Brandy, from Perry & Oliver, of Fordham, N. Y.; Grape Jelly (fine), from J. K. Brick, of Brooklyn, N. Y.; Trunk of Palmetto tree (4 feet section, 10 inches in diameter), from Lieut. N. W. Duryea, of 7th Regt., Brooklyn, N. Y.; Ice Spurs, from Mr. Lyman, of Brooklyn, N. Y.; Pieces of petrified pine (from whole tree found in marl near Fredericksburg, Va.), from F. E. O'Hearne, of Brooklyn, N. Y.; Petrified Oak (found near Fortress Monroe), from Smith Briggs, 5th N. Y. Vols.; Maple Sugar (beautiful specimen made without being cleansed or clarified by any substance whatever), from L. Woolcott, of Croton, N. Y.; Sorghum Syrup (good) from Mark Cornell, of Ford Co., Ill.; Specimens of paper made from corn-husks in Germany, from Hon. Truman Smith.

Sewing Machines.—No article of household use is so much desired as a sewing machine. So rapidly has this invention grown into public favor, that it is now considered almost indispensable to every family. Over a hundred thousand families already experience its benefits, and each week adds nearly another thousand to the list, and so the ratio of the demand increases in proportion as the advantages of the invention become known. The sewing machine of the present day is not, however, the sewing machine of some years back. Though retaining the first principles, many and valuable improvements have been added, and various modifications and alterations of machinery found necessary to increase the speed and efficiency, render it more simple and noiseless, and adapt it to all the different requirements of the family and the workshop. The Grover and Baker Sewing Machine Company, among the first to produce a practical Sewing Machine, have been most successful in attaining these results. Their machines are now to be found in almost every part of the world, and they are everywhere recognized as excellent.

The Breadstuff Markets have been materially affected by the decline and fluctuations in gold, though as shown in the tables above, the volume of business, both in receipts and sales has been fair, as compared with the same period last year. Every decline or rise in the currency value of gold affects foreign exchange, and correspondingly depresses or raises the relative value of breadstuffs for exports. (Dry Goods, and all articles imported, are doubly affected by these gold changes, for the importer pays one premium on exchange, to pay in foreign markets, and another on the gold for duties). The demand for breadstuffs has been quite moderate, both for shipment and home use; and as most holders have been eager to sell, prices have declined materially on this account. Flour has fallen 30 to 60 cents per barrel; and Wheat about 5 cents per bushel; and Mixed Western Corn 2 cents per bushel. The present tendency is toward a lower range; owing to the heaviness in the market for gold. Sterling Exchange Bills are not in much request and are quoted 1½ to 2½ per cent. lower proportionately than gold, which circumstance operates as a serious hindrance to active export movements. The shipments of domestic products, within each of the past two weeks, have consequently been on a much less extensive scale than during each week in the month of March. The falling off is most obvious in breadstuffs, the exports of provisions indicating a vigorous foreign demand for Amer-

ican hog products. The latter, however, have been very freely offered in this market at reduced prices. The annual statement of the Western pork packing business for the past season shows a marvellous result. The number of hogs packed the present season is over four million head (actually 4,069,620) being an increase over the packing of the season of 1861-62 of nearly a million and a quarter, namely, 1,176,887, or 40 per cent. The decrease in weight is 7½ per cent., leaving a net increase of over 32-5th per cent. as compared with last year. The yield of leaf lard is five pounds per hog less than it was in 1861-2, but owing to the great increase in the number of hogs slaughtered, there is an absolute increase in quantity of 27½ per cent. over last season. The demand for Wool has been quite limited, during the past two or three weeks, and prices have declined considerably. Manufacturers are afraid to buy freely, in the present unsettled state of the market for gold, which directly affects, and, to a great extent, positively governs every branch of regular business. Cotton has fluctuated materially, closing, however, tamely at drooping prices. Hay has been in fair demand at full rates. Hops and Tobacco have been quiet and depressed. There has been unusual dullness in most other commodities. The table of Prices Current show the present rates, and the changes from one month ago.

Hogs packed in the West during each of the last two seasons:

	1861-2.	1862-3.
Ohio	791,099	981,663
Iowa	205,188	403,899

Wisconsin, lbs.....	260	214	35 33½

Live Stock Market.—BEEF CATTLE HAVE averaged 4,610 head per week, which is a large supply for the Lenten season. Government agents, and shippers to Bermuda, the West Indies, and to New-Orleans, have bought pretty freely, and prices have advanced about 1c. per lb., net weight, since our last report, and are 2c. higher than a year ago. The present rates are equivalent to 11½c. @ 12c. per lb., net weight of the dressed quarter, for the best; 10c. @ 11c. for good cattle; and 8c. @ 9c. for poorer grades. New-York State is thoroughly drained of beef cattle, and with the large demand likely to continue, dealers are looking for higher prices before July.

Veal Calves come in freely, as usual at this season. The weekly receipts have averaged 785 for a month past. The higher rates for beef have benefited the Veal markets, and good calves readily go at 6½c. @ 7c. per lb., live weight; common to fair class at 5c. @ 6c.

Sheep.—The receipts have averaged 5,673 per week. The decline in wool consequent upon the decline in gold, has lessened the value of full-wooled pelts about \$1 each, and sheep are about that much lower. A few of the best fine-wooled fat sheep go at prices equivalent to 10c. per lb., live weight; ordinary to good, 8c. @ 9c.

Live Hogs.—Receipts have averaged 14,633 per week. The little demand for packing, and the approach of warm weather, depress the market. Prices now rule at 5½c. @ 5¾c. per lb., live weight, for heavy, fat, corn-fed hogs; 4½c. @ 4¾c. for still-fed; and 3½c. @ 4c. for mast-fed.

The Weather.—Since our last notes, Feb. 20, has been changeable, with a good deal of cold and wet, making the season quite backward. There was a fall of one foot of snow on Feb. 22, cold to 24, warm 25, with heavy rain 26 and 27. March 1, rain—2, clear, warm—3, rain and snow—4, cool—6 to 8, snow and rain—9, clear, sleighs out—10, 11, more snow—12 to 17, clear, cool, light rain on night of 17—18 to 20, fine, warm—21, cloudy, heavy rain at night—22, 23, clear, fine—24, cloudy, rain at night—25, hard N.E. rain ending with thunder-storm at night—26, 27, clear, fine—28, N.E. rain—29, 30, clear, cool—31, snow and rain. April 1, clear—2, cloudy, rain at night—3, clear, fine—4, 5, snow and rain—6, clear A. M., cloudy P. M., rain at night—7, rain and snow—8, cloudy—9 to 12, clear, fine, warm, rain night of 12—13, cool, cloudy—14, clear, fine—15, cloudy, rainy night—16, hard N.E. rain day and night—17, 18, cloudy, ground too wet for farm work. Some farmers have planted their potatoes, and sown oats and peas. Market gardeners have set out early cabbages.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit).—r indicates rain—s, snow.]

OFFICE OF

FISK & HATCH,**BANKERS AND DEALERS IN GOVERNMENT SECURITIES.****No. 38 Wall-st., New-York.**

AGENTS FOR THE SALE OF

THE UNITED STATES FIVE TWENTY YEAR SIX PER CENT BONDS.

The interest on these Bonds is at the rate of Six per Cent. per Annum, and is payable 1st May and November, in Gold. They are called "FIVE TWENTIES," because redeemable at the option of the Government after five or within twenty years.

The *Coupon Bonds* are issued in denominations of \$50, \$100, \$500, \$1,000, and are payable to bearer, as are also the *Coupons* for the collection of the interest. The Registered Bonds are issued in denominations of \$50, \$100, \$500, \$1,000, \$5,000, \$10,000, and are payable to the order of the holder, and registered in his name on the books of the Treasury Department at Washington. The Registered Bonds have no Coupons attached for the collection of interest, but the interest may be collected by the holder in person, or by any person having his Power of Attorney for the purpose, at any Sub-Treasury of the United States which he may designate.

We sell the Bonds for the Government, both Registered and Coupon, in any of the foregoing denominations, at the rate authorized by Congress, without any additional charge for Commission, viz.: at PAR, and accrued interest, or at PAR, with interest commencing from the date of subscription.

NOTE.—The Bonds are issued to us by the Government at different periods, and bear interest from the date at which we pay for them, as indicated by a stamp on the first Coupon. For the few days intervening between their issue and the time of sale, we charge the accrued interest, payable in Current Funds. Or, if purchasers prefer it, we take their subscriptions, and ordinarily in two or three days thereafter, deliver them Bonds, bearing interest from the date of their own subscription and payment, with no accrued interest to be paid.

We are thus enabled to save parties all trouble and expense in finding Legal Tender Notes, or otherwise investing in these Bonds.

Orders or inquiries by mail will receive prompt attention, and the Bonds will be sent to any address, by mail or express, as desired. Payment may be made in BANK NOTES CURRENT IN NEW-YORK, DRAFTS AND CHECKS ON CITY BANKS, OR U. S. LEGAL TENDER NOTES. Persons in the country can send their orders and money to us direct, or call at the nearest Bank and ask the Cashier to do it for them. Drafts or Checks may be sent with safety by mail. Bank Notes or Legal Tenders should be sent by Express.

ON AND AFTER JULY 1, 1863, THE PRIVILEGE OF CONVERTING LEGAL TENDER NOTES INTO THESE BONDS, AT PAR, WILL CEASE, AND IT WILL BE NECESSARY FOR PERSONS DESIRING TO OBTAIN AT PAR A UNITED STATES BOND BEARING SIX PER CENT INTEREST, IN GOLD, TO SEND IN THEIR ORDERS BEFORE THAT TIME.

These Bonds are the CHEAPEST GOVERNMENT SECURITY NOW IN THE MARKET, and pay the LARGEST INTEREST on their cost, and Congress has provided that they shall be paid in GOLD, when due.

They are destined to become the BEST KNOWN, MOST POPULAR AND MOST AVAILABLE, of all the Bonds of the Government.

The operation of the National Tax Law, which it is now certain will produce double the income originally anticipated, will make the issues of the United States Government the safest and most desirable investment in the world. They are in reality a First Mortgage on everything in the country, as no Railroad or Corporation of any kind, can pay a dividend, or the interest on its own issues, until it has contributed out of its gross income, through the operation of the Tax Law, to the support of the National Credit.

The present bonded debt of the United States is less than THREE HUNDRED MILLIONS, including the seven and three-tenths Treasury Notes; but the Government owes enough more in the shape of Legal Tenders, deposits in the Sub-Treasuries, Certificates of Indebtedness, &c., to increase the debt to about eight or nine hundred millions. Secretary Chase has calculated that the debt may reach one thousand seven-hundred millions if the Rebellion lasts eighteen months longer. It is, however, believed that it will not last six months longer—but even if it does, the National Debt will be small compared with that of Great Britain or France, while our resources are vastly greater.

There is no doubt that the revenue will not only be ample to pay the ordinary expenses of the Government, but all interest on the debt, but leave at least one hundred millions annually toward paying off the debt, and that the Government will be able to get out of debt again, as it has twice before, in a few years after the close of the war.

The duties on imports of all articles from abroad must be paid in GOLD. It is now being paid into the Treasury at the rate of Two Hundred Thousand Dollars each day, which is twice as much as is needed to pay the interest in Gold on all the Bonds of the Government.

The Supreme Court of the United States have just decided that the States have no power to tax the Securities of the Government. This is conclusive upon this point, and will greatly increase the value of these securities.

The money invested in the "FIVE TWENTY" Bonds through us contributes to the direct and immediate support of the National Treasury. All persons having money to invest will find it to their interest to promptly avail themselves of the opportunity to obtain them at PAR.

We also deal in all classes of United States Securities, and buy and sell Stocks and Bonds on Commission.

We pay special attention to orders from the Country. **FISK & HATCH,**
No. 38 Wall-st., New-York.

GREAT DISCOVERY.

An adhesive preparation, that is insoluble in Water or Oil and that will stick Patches and Linings to Boots and Shoes sufficiently strong without stitching. It will also mend broken Furniture, Crockery, Toys, and all articles of Household use effectually.

HILTON'S**INSOLUBLE CEMENT,**

Supplied in packages from 2 ounces to 100 pounds. It is a Liquid, and as easily applied as Common Paste. It adheres to Oily Substances firmly and completely.

Can be procured at wholesale in all large cities, and at retail throughout the country.

HILTON BROTHERS, Proprietors, Providence, R. I.
"A Good Thing."—Having occasion the other day to use a liquid Cement, we tried the article made by Hilton Brothers, Providence, and found it to work to a charm. We therefore recommend it."—*Woonsocket Patriot*, Feb. 6, 1863.

A striking picture, from life, of Eugenie, Empress of France, a beautiful woman, and Queen of the fashionable world. 3. Martha Washington, a highly finished photograph. 4. A beautiful head of our Savior. Also, Queen Victoria, the Princesses Alice, Beatrice, Helene, and Louisa, her daughters; the Prince of Wales; Empress Josephine; Florence Nightingale; Mrs. Stephen A. Douglas, a beautiful lady; Mrs. Gen. Halleck, Mrs. Gen. McClellan, and Queen of the Authors, Actresses, Singers, Dancing Girls, and Fancy Cards without number. Price 25 cents each, or five \$1.
Sent by mail, post free, on receipt of price.
A. & E. HUTCHINSON,
No. 767 Broadway, New-York.

TEETH**UPON ALLEN'S SYSTEM**

CAN BE OBTAINED AT

22 Bond-st., New-York.

By this method the TEETH, GUMS, ROOF, and RUGÆ of the MOUTH are all truthfully represented, reflecting those delicate tints, shades, and forms peculiar to the natural organs, thus concealing from the observer the human agency in forming them. This we do positively accomplish, as evinced by our numerous patrons. The natural expression of the mouth, and original contour of the face can also be restored, which rejuvenates the waning cheek.

A descriptive pamphlet may be obtained by addressing DR. J. ALLEN & SON, as above.

**THE CRAIG MICROSCOPE.**

This is the best and cheapest microscope in the world for general use. It requires no focal adjustment, magnifies about 100 diameters, or 10,000 times, and is so simple that a child can use it. It will be sent by mail, postage paid, on the receipt of \$2.25, or with six beautiful mounted objects for \$3, or with 24 objects for \$5. Address HENRY CRAIG,
150 Centre-st., New-York.

A liberal discount to the trade.

The editor of the *Sunday School Advocate* says in regard to this newly invented instrument:

"Its simplicity, cheapness, and great magnifying power struck me with surprise. Then I was examining a fly's eye by its aid, and was struck with wonder at the skill and power of the Creator which is displayed in its structure. When I saw a statement in an advertisement that the Craig Microscope magnified one hundred diameters, and could be bought for \$2, I thought it was one of the many humbugs of the hour, for I had paid \$20 for a microscope not long before. But now I find it to be a really valuable instrument, which I should like to see introduced into the families of our readers in place of the manifold useless toys which please for an hour, and then are destroyed. This microscope would both amuse and instruct them, and I advise every boy and girl who wishes to know the wonders which lie in little things, to save his money until he has \$2.25, for which a microscope will be sent him post-paid."

60 Courtlandt-st., New-York.

INGERSOLL'S IMPROVED

HORSE AND HAND POWER

HAY AND COTTON PRESSES.

These machines have been tested in the most thorough manner throughout this and foreign countries to the number of over 1200.

The Horse Power is worked by either wheel or capstan, and in many respects possesses unequalled advantages. We invite those waiting such machines to write for a catalogue containing full information, with cuts, prices, &c., or call and examine personally.

Orders promptly attended to, by addressing
INGERSOLL & DOUGHERTY, Greenpoint, Kings Co., L. I.

Wheeler & Wilson's**HIGHEST PREMIUM****SEWING MACHINE.**

WITH VALUABLE IMPROVEMENTS.
Office No. 505 Broadway, New-York.

\$200 J. P. HALE'S \$200

NEW 7 OCTAVE PIANOS are destined to revolutionize the whole Piano business. For Durability Beauty of Tone, and Touch, as well as in style of finish, they are unequalled; and nothing of the kind has ever before been offered in this country that will compare with them in prices:

\$200, — \$225, — \$250.

They contain all improvements of value now in use, and are all

Warranted for Five Years.

Please call and examine them and compare them with those of any of the first class makers, or send for a Circular giving all particulars.

J. P. HALE & CO., 478 Broadway, N. Y.

\$150. SEVEN OCTAVE \$150.**ROSEWOOD PIANO-FORTES. \$150.**

GROVESTEE & CO., 499 BROADWAY,

Now at their new warehouses, are prepared to offer to the public their new ENLARGED scale PIANO FORTES, with Iron Frame, Overstrung Bass, French Grand Action, Harp Pedal, etc. The Grovestee Pianos have received the highest award over ALL others at the World's Fair, and for FIVE successive years at the AMERICAN INSTITUTE, which is a sufficient guarantee of their excellence.

Heavy Mouldings, Carved Legs, etc., \$175 and \$200. Rosewood Tops, \$10 extra. Warranted for five years. Terms, net cash.

**The NONPAREIL WASHING MACHINE**

Is the only entirely reliable machine in use. It has been before the public two years, and has not in any instance failed to give satisfaction. It saves two-thirds the labor and time required in hand washing. It is a squeezing machine, and will not injure the finest clothing.

A girl of fourteen years can operate it. It will not get out of order. It is recommended by Mr. Judd, the proprietor of this Journal. Prices: No. 1, \$12. No. 2, \$16. No. 3, \$20. Send for free Circular to

WE CALL ATTENTION TO THE

EXCELSIOR

HORSE PITCHFORK.

FOR UNLOADING HAY, GRAIN, &C.

REISSUED MARCH 3, 1863.

This Fork was awarded the First Premium, at the N. Y. State Fair, Oct. 1862, and is universally acknowledged to be the best in use. It is a Simple, Compact, and strong implement, light and easy to handle.—Will hold as much as a horse can elevate, and frequently two are employed. A boy can use it, unloading a ton of hay in five or six minutes. In view of the scarcity and high price of labor, no farmer can afford to do without it. It will save more than its cost in a season,—sometimes in a single day.

N. B.—All persons are hereby cautioned not to make, vend or use, any other Horse Fork, with tines similar to this, or which infringe upon this Patent in any respect. For Forks, address WHEELER, MELICK & CO., Proprietors of the N. Y. State Agricultural Works, Manufacturers of Horse Powers, Threshers and Cleaners, Albany, N. Y. For State or County Rights, address PALMER & WACKERHAGEN, Greenville, Greene Co., N. Y. Circulars sent free.

GET THE VERY BEST**Horse Hay Forks.**

Every Farmer having a dozen acres of meadow will find a good Horse Pitch Fork a profitable investment.

The very best and cheapest implement of the kind is Rundell's new Patent, just issued (April 1863). Please look into its merits.

Circulars with engravings and giving full particulars will be sent free to all applicants.

Address L. RUNDELL,
Coxsackie, Greene Co., N. Y.**ALLEN'S PATENT****CYLINDER PLOW.**

Price of No. 0, is \$7.00; No. 1, is \$9.00; No. 2, is \$10; No. 3 is \$12; with one extra polished share for each plow. Price, extra, of Skim or Front Plow, \$1.50; Wrought Side Coultter and Clamp, \$1.25; Wheel, \$1.00.

All the above Plows are polished, strong, and highly finished, and are warranted to give entire satisfaction when properly managed. Polished Steel Plows can be furnished of each of the above sizes.

Also every style of the latest Improved PLOWS, HARROWS, CULTIVATORS, and a full assortment of AGRICULTURAL and HORTICULTURAL IMPLEMENTS; FIELD AND GARDEN SEEDS; PERUVIAN and MANIPULATED GUANO; SUPERPHOSPHATE, guaranteed to be the best in the market, and perfectly reliable; Poudrette; Plaster of Paris, &c.

AND

ANTI-FRICTION

HORSE POWERS,

Have taken the HIGHEST PREMIUMS WHEREVER EXHIBITED! NINE FIRST PREMIUMS being received from WESTERN STATE FAIRS in 1861.

THE MILL may be driven by horse, water, or steam power, does its work as well as the best flat stone mills in milling establishments, and requires but *one-half* the power to do the same amount of work. They are made in the best manner, and will last *thirty years*, and cost *nothing* for repairs.

THE HORSE-POWER runs upon iron balls, and requires but TWO AND A HALF POUNDS DRAUGHT to keep it in motion. With the same number of horses it will do TWENTY-FIVE PER CENT. more work than ANY OTHER POWER IN USE.

EVERY MACHINE IS GUARANTEED TO GIVE SATISFACTION, OR THE MONEY WILL BE REFUNDED.

The Student Parsnip.

This was originated or rather "ennobled" by Prof. Buckman, of the Royal Agricultural College, Cirencester, England, from the wild Parsnip a native of Great Britain. It is highly recommended by English writers, as a great acquisition. Price 25 cents per packet, post-paid.

B. K. BLISS, Springfield, Mass.

TREE COTTON SEED.

A lot of the genuine South American Tree Cotton Seed, is offered for sale in small quantities, to farmers and others, who may wish to experiment in raising Cotton in the Central, or Northern States. This seed was gained on the "DOUBLE CYLINDER SAW GIN" and "EXCELSIOR" from a small lot of cotton brought to this country from Ecuador, South America, and was raised in a climate differing but little from our own. The fibre of this cotton is very strong and nearly as long as Sea Island; it yields over forty per cent. of clean cotton. A sample of this cotton may be seen at this office, and at F. & L. Many's, 48 Warren-street, New-York. Price, one pint, containing about 1,500 seeds, \$1; one quart, \$1.75; one peck, \$10. One hundred seeds put up in an envelope, will be sent to any address, postage paid, for 25 cents. Orders may be addressed to

EDWARD F. BROWN,
New-London, Conn.
or F. & L. MANY, 48 Warren-st., New-York.

Two New Publications FOR THE MELODEON, HARMONIUM, CABINET ORGAN, & C.

The great and rapidly increasing popularity of these instruments, which have been brought to such a high degree of excellence as to elicit the warm commendation of artists, and to merit a place in every drawing-room; and the frequent complaint of the inaccessibility of suitable arrangements and selections from the best works of the great masters, for such instruments, have induced these publications.

I.
SCHOOL FOR THE MELODEON, HARMONIUM, AND CABINET ORGAN; containing Progressive Lessons, Studies, and Scales; Songs, Duets, Trios, and Quartets; Voluntaries, Interludes, and Recreative Pieces; for the Parlor and Choir; carefully prepared with reference to the advancement of Learners, both in technical ability and taste as well as the true development of the powers and beauties of these instruments. By **GEORGE F. ROOT.**

This work is not a compilation from Piano Forte instructors, but its arrangements are all carefully adapted to the sustained tones of the instruments for which it is designed. Beginning with the simplest lessons possible, *one thing is introduced at a time*, the course of instruction being carefully progressive throughout. It varies very materially from all previous instructors for these instruments, and it is hoped will be found to supply a want long felt by learners and teachers. One quarto volume. Price \$2.

II.
RECREATIONS FOR THE CABINET ORGAN, HARMONIUM, OR MELODEON; consisting of Selections of the most Popular Themes, from **ALBANY, BEETHOVEN, BELLINI, DONIZETTI, HANDEL, MOZART, ROSSINI, SPOHR, VERDI,** and others. To be published in a series of six numbers, of sixteen pages each, with cover. The first number will appear Saturday, May 2d, and succeeding numbers every other Saturday thereafter.

CONTENTS OF NUMBER ONE:
DUCHESS OF OLDENBURG'S HYMN, arr. by C. Heineman; **CHORUS FROM MASSANIELLO,** Auber; **HYMN FROM STRADELLA,** Flotow; **ARIA FROM RIGOLETTO,** Verdi; **LARGHETTO FROM MAGIO FLUTE,** Mozart; **SONG BY KUCKEN;** SERENADE FROM STRADELLA, Flotow; **CHORUS FROM A NIGHT IN GRANADA,** Kreutzer; **BALLAD FROM ZAMPA,** Herold; **LORELEY;** **ARIA FROM ROMEO,** Bellini; **PORTUGUESE HYMN,** arr. by Novello; **NOCTURNE FROM MARTHA,** Flotow; **GERMAN NATIONAL SONG,** arr. by C. Heinemann.

Price 30 cents per number, or \$1.50 for the series, on receipt of which they will be sent post-paid, to any address. Published by **MASON BROTHERS,** New-York. Boston, Mass., **MASON & HAMLIN.**

Grape-Culture and Wine-Making.

HARPER & BROTHERS,
FRANKLIN SQUARE, NEW-YORK,

Publish this Day:

HARASZTHY'S WINE-MAKING, &c. Grape-Culture and Wine-Making: being the Official Report of the Commissioner appointed to investigate the Agriculture of Europe, with especial Reference to the Products of California. By **A. HARASZTHY.** Maps and illustrations. 8vo., Cloth, \$5.00.

Sent by mail, postage free, on receipt of \$5.
The author of this work, himself a vine-grower on a large scale, was appointed by the Legislature of California as commissioner to visit Europe to investigate the ways and means best adapted to promote the improvement and culture of the grape-vine in California. He visited in succession the chief wine districts of France, Germany, Spain, and Italy being familiar with the process of wine-making as practised in his native Hungary. His credentials gave him ready access to every means of information. The proprietors of the leading vineyards and wine establishments afforded him every facility for investigation, and he collected in addition a vast amount of material in the shape of reports and treatises upon the subject. The most important of these are embodied, either in full or abridged translations, in this volume, which abundantly attests the rare zeal, fidelity, and intelligence with which he performed the duties of his commission. Few more readable books of travel have been produced than that portion of the work which describes his own personal experiences and observations. He always keeps in view the special object of his journey, describing fully and clearly all the processes employed in the culture of the vine, the gathering of the grapes, and the fabrication of wines: noting also all other subjects which could relate to the agricultural interests of his adopted State. The statistics of the wine-culture, which he has laboriously collated, are something remarkable.

TOBACCO.

Just How to Grow it.

Every particular, from the selection of the Seed, and preparation of the ground, to the Gathering, Curing, and Marketing the Crop, is given in a work issued by the Publisher of the *American Agriculturist*, and sent post-paid for 25 cents. This work consists of a selection of the best fourteen out of eighty-five Essays, prepared by eighty-five different cultivators, residing in various parts of the Northern and Middle States. In each of the Essays contained in this work, the writer tells, in a plain, practical, straight-forward manner, just what to do, and how to do it. Any item omitted by one is given by another, so that the information is full and complete. Several engravings illustrating the method of drying, packing, etc. The work is worth its weight in silver to every one growing even a small plot of tobacco.

Webb South Down Sheep, AT PRIVATE SALE.

I have now on hand for sale, a superior lot of yearling rams, and a few of different ages to rent. My yearlings are heavier woolled than ever before. I shall also sell a few ram and ewe lambs when old enough, say in September. Circulars giving particulars ready in May, for which please address me at Holmdel, New-Jersey. **J. C. TAYLOR.**

Southdown Sheep.

I offer for sale my Flock of PURE BLOOD SOUTHDOWN SHEEP, consisting of
28 Ewes, 2, 3, and 4 years old.
2 Rams, 2 and 3 years old.
17 Ewe Lambs, six weeks old.
18 Ram Lambs do. do.
The EWES took the first premium at the Westchester Co. Agricultural Fair last Fall. Address
WARREN LELAND,
Highland Farm, Rye, Westchester Co., N. Y., or
Metropolitan Hotel, New-York.

Ayrshires.

Three thoroughbred Bull Calves, from the best milking stock, for sale by
Pedigrees given. **H. S. COLLINS,**
Collinsville, Conn.

ALDERNEY STOCK. THIRTY COWS, HEIFERS, and heifer calves for sale. Apply to
JOHN T. NORTON, Trustee, Farmington, Conn.

MALTESE JACKS.—Two just imported, one over fourteen hands, for sale by **S. B. CAMANA,**
70 Pine-street,
or **E. C. ESTES,** 22 Cedar-st., New-York.

TO FARMERS AND OTHERS.

We are manufacturing a Genuine Article of FINE, MEDIUM, and COARSE BONE DUST, or RAW BONE SUPERPHOSPHATE OF LIME, manufactured from unburned Bones, containing all the Animal and Chemical Fertilizing Properties. Please address the Manufacturers, and get the Intrinsic Value of your money.

N. B. A Liberal Discount made to Dealers for Cash.
Address **A. LISTER & BRO.**
Tarrytown, Westchester Co., N. Y.,
Or Newark, N. J.

100,000 BARRELS OF THE LODI MANUFACTURING CO'S POUDRETTE.

FOR SALE BY

JAMES T. FOSTER, No. 66 Courtlandt-st., New-York.
This article, prepared from the night soil of the city of New-York, is the CHEAPEST, BEST, and MOST POWERFUL FERTILIZER offered in the market. It greatly increases the yield, and ripens the crops from two to three weeks earlier, at an expense of from \$3 to \$4 per acre.
Also, FIFTY TONS OF BONE TA-FFW, being a mixture of bone and night soil, ground fine, at \$45 per ton. A superior article for grain and grass.

A pamphlet containing directions, &c., may be had free. Address
JAMES T. FOSTER,
Care of Lodi Manufacturing Company,
No. 66 Courtlandt-st., New-York.

POUDRETTE.

Farmers and Dealers supplied with a pure article.
Send for Farmers' Agricultural Almanac for the year 1863.
GRIFFING, BROTHER & CO.,
60 Courtlandt-st., New-York.

RHODES SUPER-PHOSPHATE, THE STANDARD MANURE.

Prepared from Bones treated with Sulphuric Acid, uniform in quality and regular in price.

OATS, CORN, TOBACCO, AND ROOT CULTURE, ALSO TOP-DRESSING ON THE GROWING WHEAT. "RHODES"—the long established MANURE in the American market, besides having European reputation, can not be excelled for the above seasonable crops.
Our usual large stock now ready for delivery. Dealers and farmers apply to **HENRY E. MORING,** General Agent,
97 Pearl-st., near Hanover Square, New-York.
Or **B. M. RHODES & CO.,**
82 South-st., Bowly's Wharf, Baltimore, Md.

COE'S SUPERPHOSPHATE OF LIME.

Pure Bone Dust.

The exorbitant price of Peruvian Guano, makes these the cheapest and best fertilizers which the farmers can use.
OTHER FERTILIZERS OF ALL KINDS.

R. H. ALLEN & CO.,
New-York Agricultural Warehouse and Seed Store,
189 & 191 Water-st., New-York.

HOYT'S AMMONIATED BONE SUPERPHOSPHATE OF LIME. A Substitute for Peruvian Guano. Sold at wholesale and retail by
GRIFFING, BROTHER & CO.,
60 Courtlandt-st., New-York

GUANO.

117 TONS OF GUANO from Saldanah Bay, a superior article, for sale at the low price of \$25 per ton, to close a consignment. Apply to
WM. H. ROSS,
No. 704 Broadway, New-York.

Good Grape Vines,

FOR A FEW DAYS LONGER.

The offer of Delaware and Concord Grape Vines made last month, will continue open in May just as long as it will do to send the vines by mail or otherwise. We have kept them back from starting, by covering in a cool place, and if the weather continues as cold and backward as hitherto, the vines can be safely sent up to the 10th, and even to the 15th or 20th of May.—Let all who desire a grape vine or two, or more, of the very best out-door sorts, embrace the present opportunity to get them without expense, by sending one or more subscribers. There are plenty of persons who ought to take and read the *Agriculturist*, and many would do so, if their attention was drawn to it, especially at the beginning of the Summer work. As soon as any person becomes entitled to premium vines, a circular of Directions for Culture, etc., will be forwarded, and the vines will follow in two or three days, (without waiting a week as indicated in the circular).

Another Offer.

Any premium vines secured during May, but too late to be sent this Spring, will be kept growing in our own grounds during the Summer, and will be forwarded as early in Autumn as it will do to send them, (one for each subscriber received this month at \$1 a year.) The vines will be much larger then, but the postage will be only half as great. Here is a chance, then, to help enlarge our subscription list all through this month, and in return for the trouble, get the premium vines next Autumn. This offer is only made for the month of May, or June, at the latest. All premium offers of every kind will close at the middle of the volume, (in July.)

Strawberry Premiums,

EXTRA.

We are growing several varieties of improved strawberries, and are on the look-out elsewhere, for any new kinds that prove valuable. Last Summer we distributed 40,000 plants of the Triomphe de Gand Strawberry, as premiums, (10 or more for each new subscriber,) sending them to all parts of the country with remarkable success. The postage on plants will be reduced one-half after July 1, and we propose to send out some more good strawberry-plants as premiums to those who will during May and June procure and forward subscribers to the present volume of the *Agriculturist*, at \$1 a year. The Triomphe de Gand will be distributed, in part, if nothing better or more desirable is found. In July, or after seeing the fruit and observing the plants this season, we will announce what kinds will be distributed. Those desiring the strawberry premiums will please name the fact when sending in subscribers, that their names may be put down for that purpose, and they may feel assured that they will be liberally dealt with—at least as well as in the strawberry distribution last year.

An Exhibition of Pumpkins, Squashes, Gourds, etc., will be held at the American Agriculturist Rooms, next Autumn, of a similar character to the one last year, but probably on a still larger scale. The list of prizes, and other particulars, will be given hereafter. We merely mention the matter now, that cultivators may be preparing for it in season. Who will raise the largest Pumpkin or Squash, the greatest yield on a vine, the best varieties for eating, the finest collection of Ornamental Gourds, etc.? Don't let Connecticut get more than one first premium.

Books Not Advanced.—By reference to the list on page 159, it will be seen that the prices remain the same for May as for April, with two or three exceptions. Several are struck out because no longer issued, and some additions are made. This list is good only for the month in which it appears, as during the scarcity of paper, publishers are continually advancing prices, and suspending publication of many books.

The Special Premiums.

EXPLANATION.

Our readers will notice that we are offering Special Premiums at this season. The fact is, we are making every possible effort to increase the subscription list to the highest possible point, in order to fully meet the greatly increased cost of printing paper, and of other publishing expenses, without raising the subscription price. Our general expenses, aside from printing paper and press work, are not now increased by additions to our list, hence there is an advantage derived from every new name now received, even after paying the special premiums. We think the paper is better than ever before, and in view of the fact that the price remains the same, we shall be greatly obliged to all our friends who at the present time aid in rolling up the list. Can we not have a hundred thousand subscribers this year? A single addition from one half of our present subscribers would more than secure this desirable result. At this season, many will feel the need of all the hints they can get, and they will perhaps be the more ready to take and read the *Agriculturist*. The premiums offered, will, we hope, be considered as a partial remuneration, at least, for the trouble taken by our friends in soliciting subscriptions from others. As a rule, we do not expect hereafter to give any premiums not offered at the beginning of the year. All premiums offers of every kind close in July.

Read the Advertisements.—We are sometimes asked where to procure articles, which are already advertised in our columns. As the advertisements often announce novelties before they are noticed editorially, they are generally profitable to look over. Our advertising pages have been pretty thoroughly weeded by the standing rules. We repeat the suggestions, to study over the business notices, and send for the catalogues and circulars offered, and thus learn what is for sale, on what terms, and by whom; also please let the advertisers know where their business cards are seen by the largest number of wide awake readers. They like this plan.

Back Volumes & Numbers For Sale.

We have complete sets of Vols. 16, 17, 18, 19, 20, and 21, both unbound, and bound in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, 20, and 21, unbound.....\$1.00 each.
Volumes 16, 17, 18, 19, 20, and 21, bound.....\$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.

(They can not go unpaid.)

Volumes 16, 17, 18, 19, 20, and 21, unbound.....\$1.12 each.
Volumes 16, 17, 18, 19, 20, and 21, bound.....\$2.00 each.

BINDING.—Sets of numbers sent to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 12, to 21 inclusive, at 25 cents per cover. Covers can not go by mail.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, etc., and to HOUSEHOLD LABORS, with an interesting, instructive department for CHILDREN and YOUTH.

The Editors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST are confined to no State or Territory, but are adapted to all sections of the country—it is for the whole AMERICAN CONTINENT.

A German edition is published, of the same size and price as the English, and containing all of its reading matter, and also its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE.

(For either the English or German Edition.)

One copy, one year.....\$1 00
Six copies, one year.....5 00
Ten or more copies one year.....80 cents each.

Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is only six cents a year, if paid in advance at the office where it is received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

VOLUME XXII—No. 6.

NEW-YORK, JUNE, 1863

NEW SERIES—No. 197.

Entered according to act of Congress in the year 1863, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York.
Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist*.

Suggestions and Notes for the Month.

In no month of the year, are the poetry and prose of farm life more mingled, than in the present. Earth, air, and sky, are full of inspiration. Each element seems striving to express the joyous fullness of life which Spring only awakened. The fervid glances of the sun are answered by blushing fields of beauty upon the earth. The morning and evening clouds seem to vie with the plains beneath in producing exquisite scenes for the eye of the artist. Light-footed zephyrs dance along the plains, their tresses laden with perfumes showered from orchard and forest. Joyous notes echo from the flocks and herds upon the hillside, and a perpetual chorus of song from the blissful birds reminds the hearer of heavenly symphonies. It is a striking fact that in nature the period of the greatest activity is accompanied with the highest display of beauty. When her most important works are to be executed, her servants don their holiday attire. Those gorgeous clouds are her industrious water-carriers; the refreshing breezes that sweep across the fields, convey nutriment to the myriads of leaves that the genial sun has called forth; and these, so radiant in their livery of green, are each rapidly elaborating the nourishment that shall add to the parent growth. The bees that so gaily hum from flower to flower, are not only gathering provision for their own sustenance, but distributing the pollen by which the flowers are to be fertilized, and without which, in large measure, their beauty would be fruitless. The birds, in addition to filling the air with sweet sounds, are, with watchful eyes, guarding the fields from depredations which no human scrutiny or skill could avert. On every tree, shrub, and flower, voracious insects are preying, that the superabundance of vegetation may not itself become noxious; but, unchecked by the

birds, these otherwise useful little creatures become a most intolerable pest. Thus, in every field, labor and the signs of rejoicing go hand in hand. Surely this is the visible testimony of the Creator to His estimate of labor; it is His proclamation of the design that happiness shall be found, not in passive reception of outward appliances, but in the active use of the faculties He has bestowed. Surely as we rise in the scale of being, the enjoyments of toil should be heightened. If the birds sing while laboriously gathering food for their young, shall not man be joyful while pursuing his nobler avocations? But the picture has its prosaic background. It is delightful to sing of pleasant fields, but not so enlivening to hoe corn. The flowers are charming to look upon, but the cultivator finds little delight in them when, on the thistle and the daisy, they require vigorous work for their extirpation. Much of pleasure will be found in the poetry of the month, and the more its perception is cultivated, the more may the husbandman be cheered in his toil; but he finds that stern purpose is needed to hold him to the heavy task of field labor. He may be encouraged by the thought that his work now is only preparatory. His time of joy will come when the fields shall have been despoiled of beauty, the birds ceased their song, and the winds only sigh over the ended harvest. He should also be nerved to patient endurance by the knowledge that his end is higher than merely to change the form of outward things. By industry and its accompanying virtues he is working out a character whose development but commences here. He is sowing seeds that are to spring up, and blossom, and bear perennial fruit in a land that knows no Winter, where activity and enjoyment are co-eternal.

Work for the Farm, Household, etc.

The labors of this month will in large measure decide as to the excellence of the great staples, corn, potatoes, and other hoed crops. If the weeds be kept in check, and the soil mellow, a favorable season will do the remainder. Without good tillage, it is vain to expect more than a light crop, however propitious the weather may be. Thorough cultivation will go far to make up for what may be lacking in weather, and also in the richness of soil. A good hoeing is equivalent in its effects to no small amount of manure. As far as practicable substitute horse power for hand labor. A good cultivating instrument will save one or more hired hands, and thus more than pay for itself in these times of scarcity of men.

Barns and Sheds will soon be needed for hay and grain crops. Clear out all rubbish, have floors and scaffold-poles in order, and everything in readiness before the pressing work of haying and harvesting commences. Much labor may be saved by properly grading the grounds in front of the entrances where loads

are to be drawn in. We have seen a large hay crop taken in where each load must be jerked over a rise of several inches at the door-sill. Where large quantities of hay are to be stored, it is well to provide board tubes with holes pierced in the sides, to be set upright in the mows, to secure good ventilation.

Barn-yards.—Cattle-droppings deposited during the Summer should not be allowed to dry out and partially waste. Cover the ground with muck, and plow it over once a month, or oftener, to incorporate it with the manure. Now while the yards are nearly empty, arrange for draining. Convey wash from the manure to adjoining fields, where it should be spread by small channels, to prevent too rank growth.

Beans.—Plant where corn has failed, and in orchards needing tillage. Read article on p. 177.

Bees.—This is an important month with them. For full directions, see "Apiary" on page 164.

Beets.—Sow mangel-wurzel and sugar varieties for feeding next Winter, if not already done. Read "Try a Few Roots," on page 177.

Butter made this month is usually considered the best produced during the year. Pasture is fresh and abundant, cows have regained their strength, and with right management everything is favorable to an abundant flow of rich milk. A little painstaking in the dairy will make a large difference in the cash returns. For large dairying a building devoted to the purpose is indispensable. It will greatly facilitate operations to have spring water in or near the premises. The temperature of the milk and cream should be kept uniform at about 55°. Observe the utmost cleanliness in every department. Vessels for milk or cream should be scalded immediately after use, thoroughly dried, and well aired. Keep tin utensils bright; they are preferable to wood, for receiving milk. See "Which are the Best Milk-Pans?" on page 181. New tubs should be scalded with buttermilk before using, to remove the taste of the wood. Have all vessels for packing and marketing neatly painted, or scoured bright, and plainly marked with the owner's name. Butter made this month may, with proper care, be kept until Winter, when much better prices can be realized. See p. 181.

Cabbages for late crops may be planted out through the entire month. See Calendar for last month, and also page 172, this number.

Calves may be gradually induced to drink sour milk, and also oatmeal and milk or water, by adding a little at a time to their feed. This, with good sweet pasture, will keep them thriving. A calf well cared for during the first year or two, will be every way superior to an animal neglected at this important season of growth.

Carrots.—Although late, a fair crop may be realized during a favorable season, by sowing early this month. Thin to six inches apart, and keep

well hoed. The work may be much facilitated by a carrot-weeder worked by horse power, or if hand labor be employed, by a broad-bladed hoe constructed especially for the purpose.

Cattle.—Keep working cattle in good condition through the season, by feeding grain as needed, and allowing plentiful pasture. Do not allow them to run in the road, away from your own premises.

Corn.—Owing to the late season, much will probably remain to be planted early this month. The R. I. Preminn and Improved King Philip are quick-maturing sorts, suitable for late planting. An early growth may be hastened by dropping ashes, superphosphate, or guano, in the hill. These should be mixed and covered with soil; the seed would be injured by contact with them. Soaking and tarring the seed, and drying with lime or plaster, will also hasten germination, and aid in repelling birds and insects. From its first appearance above ground, corn should be kept free from weeds, and the soil loose. Leave not more than four stalks to the hill, and replant all missing hills. A top-dressing of ashes and plaster upon the hills, and guano scattered between the rows and plowed in, will be of service in feeding the crop, especially upon light soils. Corn is a gross feeder, and worn-out soil can scarcely be too highly manured.

Cotton.—Cultivate as directed above for corn.

Grain-Fields.—Mark the earliest and best portions to be harvested separately for seed, and take out weeds by hand before the grain is headed out. In Southern localities cutting may commence before the close of the month. Wheat and rye are ripe enough for harvest, when the berry is just out of the milk, and firm enough to bear moderate pressure of the thumb-nail without breaking.

Haying is too often delayed until the grass is over-ripe. Cut grass and clover when just passing out of bloom. If left later, much of its nourishing substance is converted into woody fibre of little value for feeding. Mowing machines, horse-rakes, and horse pitchforks, will be of great service during the present year of scarce help. They will pay on all farms where there is much grass to cut. Hay caps will in most instances pay for themselves in a single season. They not only save much damage from rains, but by their use grass can be cured without deterioration from dew, and kept uninjured until hauling can be conveniently attended to. A good barometer will also be of great service in determining when it is safe to cut largely.

Horses.—Give feed according to amount of work required. It is poor economy to keep a hard-working horse on grass. Mares with young foals do best upon green feed, with an allowance of oats.

Manure-making is in order at all seasons. Keep the pigs at work composting. Pile up cattle-droppings in the yard and cover them with muck, or spread plenty of muck in enclosures, to be occasionally turned over with the plow. Add all weeds and refuse from the garden and the vicinity of the dwelling to the compost heap. Arrange the privy so that its deposits can be made available. When there is opportunity, dig out muck from swamps, to be dried during the season and carted to the barn-yard in Autumn.

Millet sown any time before the middle of this month will yield a supply of forage for feeding green in August, or it may be cured for winter use.

Pastures.—Follow instructions in May Calendar.

Peas sown the first of June will yield excellent food for swine, to be fed green with the straw, or ripened, and fed alone or ground with oats.

Potatoes.—Keep well hoed until blossoming. Hill moderately if at all. High hilling induces the setting of additional tubers along the stem, which yield only "small potatoes." Top-dress liberally with ashes and plaster, or with lime alone.

Poultry.—Keep them in the poultry-yard until after noon, that they may deposit their eggs in the appropriate place. Scattered hens' nests are a premium to skunks and other prowlers. Allow none to sit after the middle of this month. Allow

young chickens access to the garden and fruit-yard, to destroy insects. Cleanse and whitewash their apartments frequently. Liquid manure made from their droppings is an excellent application for vines and other plants in the garden.

Rutabagas and Swedish Turnips should be got in during the latter part of the month. Read the article "Try a few Roots," given on page 177.

Sheep and Lambs.—Wash, if it must be done, as soon as the weather admits. Read article on this subject on page 170. Trim off all tag-locks and filth before shearing. Mark each ewe plainly, immediately after removing the fleece, and designate superior ewes to be retained as breeders. Dock and castrate lambs if not already done, and guard against the fly by smearing the wounds with tar. See "Cure of Foot-Rot," page 171, this number.

Sorghum for forage may be drilled in or sown broadcast any time this month. Cultivate like corn.

Sugar Beets and Mangels.—See article on p. 177.

Swine.—Keep them growing with plenty of sour milk, and a little grain or bran. Allow them the range of the orchard, which they will cultivate sufficiently, and greatly benefit by destroying grubs and insects in unsound fruit as it falls.

Tobacco.—Transplant about the middle of the month, according to season and locality. For full directions see Prize Article on page 108, (April number); also, the work on Tobacco Culture published at this office, as noticed in the advertisements.

Tools.—Save hired help by using the best implements—those worked by horse power, as far as practicable. Provide all the necessary utensils before commencing the haying and harvesting.

Weeds need only neglect to thrive vigorously.

Orchard and Nursery.

The backwardness of the Spring has prolonged the season of filling orders much beyond the usual time, but with the exception of sending out evergreens, the business is well over, and the nurseryman can give his attention to the remaining stock. Nursery rows will need the plow or cultivator to be run through them and the hand hoe should be used between trees. Good nurseries show no weeds.

Birds should be looked upon as the friends of the fruit culturist and no mischievous boys should be allowed to molest them on their nests.

Budded Stocks should be looked after, and the vigorous growth from the bud securely tied before it is broken by the winds or by its own weight. Remove all suckers that start from the stocks.

Evergreens.—As noted on page 179, may still be removed if the roots are kept from drying.

Grafts should be examined and grafting wax replaced where needed. Remove all suckers which spring from the stock; they will rob the graft.

Insects.—Especial vigilance is needed this month. We have given elsewhere articles on the cureulio and scale insect. The tent and other caterpillars should be watched for, and their nests destroyed. A brush made for the purpose is very useful in removing them, or a swab wet with kerosine oil may be used. Look after them early in the morning when they will be found "at home."

Layers may be made of evergreen and deciduous shrubs and trees—a good way to get strong plants.

Manure.—Give to bearing trees a generous quantity of that well decomposed. Our best cultivators are yearly more in favor of surface manuring.

Mulch all newly planted trees, evergreens especially, by covering the ground as far as the roots extend, with straw, sawdust, chips, or other litter. This will keep the soil moist and save watering.

Pruning.—For deciduous trees, next month is preferable, though it may be done at the last of this month. Attend to young orchards, cutting out all limbs that cross and chafe others, and thin out the center. Do not cut for the sake of cutting, but with an object. Aim to leave the tree compact and

well balanced with the center, not too much crowded. Do not trim off the lower limbs so as to leave a long naked trunk. Many evergreens naturally take a pleasing shape, while others need the knife. Straggling shoots should be shortened in, and all shoots which have a tendency to interfere with the main leader should be removed. Do not trim off the lower branches unless injured or diseased. The most beautiful evergreens are those which have their lower limbs spreading out near the ground.

Seedlings of nursery stock, especially evergreens, need shading. This can be done by branches laid across a rude frame, 3 or 4 feet above the bed, or by sticking leafy twigs rather thickly over the surface of the bed, to give partial shade to young plants.

Pinching should be done upon such shoots of pear and peach trees as tend to grow too long; this will induce the formation of more fruit buds.

Thinning.—Where more fruit has set than can be well grown and well ripened, thin them out freely.

Weeds.—The nursery should be kept entirely free of weeds, not only between the rows, but among the plants in the rows. Small weeds die easiest.

Black Knot.—Cut off infested limbs as soon as the knot appears. Free use of the knife, and burning the cuttings will eradicate this if done in time.

Kitchen Garden.

[The hints offered in these pages are adapted to the latitude of New-York and westward to and through central Iowa. The slight variation needed will be made by those residing northward or southward.]

This month brings abundant labor, but it is cheered by the rapidly increasing returns which the garden is making. The table should every day present a pleasing variety afforded by the garden. Asparagus, greens of various kinds, lettuce, cress, and radishes, and an abundance of rhubarb for sauce and pies, contribute to our present enjoyment, while the later crops are full of promise for the future. Whoever would know what good vegetables are, should have them seasoned with his own labor.

Asparagus.—The cutting should not be continued beyond the middle of the month or the roots will be injured. Hoe off weeds and let the shoots grow.

Beans.—Continue to plant. See article on page 177. Limas, if planted early this month and stimulated by liquid manure, will ripen the crop.

Beets.—The main crop should be put in by the middle of the month. Hoe, weed, and thin those planted earlier. The young beets, roots and tops, are by many persons preferred to all other greens.

Cabbage and Cauliflowers.—These, together with the rest of the tribe, such as kale, broccoli, and brussels-sprouts, need similar treatment. Transplant as soon as large enough. Seed put in as late as the first of the month will in most seasons make a crop. All these plants are subject to the attacks of various insects, as mentioned in an article on page 172. Give all frequent hoeings. When there is a spare moment, hoe cabbages, etc.; it will pay, and so will a frequent persuasion of liquid manure.

Carrots.—If the backward season has prevented an earlier sowing, seed put in now will make a good crop. Hoe and thin early. Thin from four to six inches in the rows. Work this and all other root crops before the weeds get the start.

Celery.—Prepare trenches and set out early plants as directed last month, on page 146. Some cultivators raise the plant upon the surface and blanch it by earthing up after it is grown. It is found that the flavor is much less delicate when treated in this way. To get stocky plants for the late crop prick out the seedlings into another bed.

Corn.—If long cold rains, such as have prevailed around New-York, have injured the early planting, loose no time in rescuing the ground. Continue to plant for succession every ten days or two weeks until the 1st of July. There is nothing better than the Stowell for the late and main crop. Manage to have a full supply to dry for winter.

Cucumbers.—These, like children, require great care until they can run alone. The striped bug is the great enemy. The protecting frames directed in last month's Calendar, the free use of ashes, plaster, or lime, and hand picking early in the morning, must be relied upon as preventives. Their rapid growth must be forwarded by frequent hoeings and the application of liquid manure during moist spells. The cucumbers will soon get out of reach of the bugs which prefer young and tender plants to old ones. It is advantageous to put in seeds at intervals of a few days, to furnish a supply of tender leaves to attract insects from the older plants. Cucumbers for pickles should be planted this month.

Egg Plants.—Plant out as soon as cool nights are over. Have the bed well enriched, hoe frequently, and give liquid manure. The crop is late at best. Take every pains to promote rapid early growth.

Endive.—Sow for Summer use, and thin out or transplant in the same manner as for lettuce.

Insects.—This is emphatically the war month in the garden, and as the insects go through the different stages of egg, larva, pupa, and perfect insect, a "change of base" will be required in our campaign. The destruction of a moth or other perfect insect prevents deposition of eggs, and the crushing of a cluster of eggs saves future trouble with the larvæ. The careful observer will see frequent opportunities for nipping trouble in the bud, and be able to keep down his insect enemies. Crushing the eggs, trapping or catching the moths and beetles in open bottles of sweetened water, dusting the larvæ with lime or ashes, or drenching with soap-suds are the principal tactics to be practised.

Lettuce.—Plant in unoccupied places for succession. If possible put the later transplantings where they will be shaded during the heat of the day. As the season becomes hotter, lettuce runs to seed early and must then give place to endive.

Melons.—These require essentially the same care as cucumbers. Both are benefited by pinching off the leading shoot to induce the formation of side branches on which the fruit is chiefly borne.

Onions.—Forward their early growth by hoeing, weeding, and thinning to 3 or 4 inches in the rows. In some localities the maggot of the onion fly causes great injury to the crop. This Spring a small pamphlet was published by S. Truesdale & E. R. Coburn, Manchester, N. H., which for a dollar gave their specific for destroying the maggot. Being published in this way we did not feel at liberty to copy it, but we find that other agricultural papers have made free use of it, and we see no impropriety in copying the following account from one of our exchanges: "Take a good, strong barrel, and go or send to some gas-works and get the gas-water, which is generally thrown away. The expense per barrel, even to those who send one hundred miles for it, will not be more than three dollars, and to those who live near a city or considerable village, the expense will be very trifling. To every barrel of this gas-water, add fifteen pounds of newly slaked quick-lime, and the same proportion for less quantities. Be sure and keep it air-tight, so that it may not lose its strength. When the time has come to use it, draw out into a tub a few gallons, and add to every gallon of the liquid two gallons of pure water, and use up immediately. Do not let it remain open to the air longer than is needful. A little variation in preparing this Specific will make it either too weak, when it will not destroy the larvæ or maggots, or too strong, when it will kill the onions. In applying the above specific, first cover the rows of onions with pine sawdust—hard pine is best—no matter if the young plants are entirely covered up. Now keep a sharp look-out for the ravages of the maggot as the third leaf or blade starts up. As soon as appearances of it are seen, go through the rows, and apply the specific with a watering can. If the maggots do not disappear, apply it the second, and if necessary the third time. The liquid must go directly on to the bulb to be effectual in destroying the maggot, and the application should be

made in the morning, or after a rain."—So runs the prescription; we can not vouch for its utility.

Parsnips.—Sow early this month, if the weather has prevented doing it earlier. Hoe, thin, and weed as soon as large enough. Thin freely and give plenty of room. Some of the finest of last year's crop should have been left for seed, if home grown.

Peas.—The main crop may be put in the first of the month. Put brush to all before they fall over. Try Bishop's Long Podded, or Harrison's Dwarfish, or some other good dwarf sort. Keep well hoed.

Potatoes.—Cultivate thoroughly, and give a handful of plaster to each hill, if not done before. It does not pay to cultivate late varieties in gardens.

Radishes.—Continue to sow seed in vacant spots.

Rhubarb.—The bed will now yield an abundance. If there is more than can be used, bottle or dry a supply for Winter. Cut off the flower stalks as fast as they appear, and cultivate well around the plants.

Squashes.—If the first planting has failed on account of excessive rains, put in fresh seed. Dust with ashes, etc., to keep off the striped bug; hand-pick the squash bug, and crush its eggs. See article on squash vine borer, page 173, this paper.

Sweet Potatoes.—In many localities the first of this month will be early enough to set out the plants. Ample directions are given in April and May numbers. A correspondent in Connecticut takes us to task for recommending growing them north of New-Jersey. He tried once and failed. We saw last year a good crop raised in Michigan, where the season is much shorter than it is in Connecticut.

Tomatoes.—Transplant for the main crop. Pinch back the rampant growers. The plants may be trained to trellises, or allowed to trail upon brush, or lie upon the ground. The fruit ripens earlier if the vines are allowed to fall over. In this case cover the ground with straw to keep the fruit clean.

Weeds.—No weed is allowed to grow in a well kept garden. Use the hoe or cultivator as often as necessary, and work close to the plants with the bayonet hoe. Let no weed perfect its seed. See the articles in another part of the present number.

Fruit Garden.

Blackberries and Raspberries.—Keep well tied up to stakes or trellises. Vines planted this season should not fruit. Allow only those shoots to grow which are needed for fruiting next year, unless it is desired to multiply them. Keep free from weeds.

Currants.—By pinching out superfluous shoots much pruning can be avoided. Water with soap-suds and keep the ground loose around them. Where there is a market for green fruit it often pays better to sell currants before they are fully ripe.

Gooseberries should receive the same care as currants. Use sulphur if mildew appears. Mulching is beneficial: the size of fruit may be increased by thinning the berries, and shading from hot sun.

Grapes.—We gave hints upon the care of young vines, in the last number. Fruiting vines need frequent care. By pinching out superfluous shoots much pruning can be anticipated. The ends of bearing shoots should be shortened to within two or three buds of the last cluster. If there is a tendency to overbearing, thin out freely. One bunch to a spur will produce finer fruit than if three are allowed to grow. Look out for caterpillars and destroy them by syringing and by hand picking.

Pears.—If the dwarfs planted this Spring had fruit buds, they should not be allowed to bear. Pinch out superfluous shoots and shorten those tending to make too much wood. Use whale oil soap or air-slaked lime to destroy slugs.

Strauberies.—Clean the beds of weeds and give a mulching to keep the fruit from being soiled by contact with the ground. Saw-dust or tan-bark will answer, but perhaps the most available mulch and one which answers as well as any, is straw cut as for feeding. In picking the fruit, only careful hands

should be employed, and if it is to be marketed it should be picked directly into the box or basket in which it is to be sold. Very convenient and cheap wooden fruit boxes were advertised last month.

Flower Garden and Lawn.

The heavy labor in this department is over, and the cultivator is already receiving dividends on his investment. The fresh foliage of the trees, the welcome green of the lawn, the early flowers of the garden—always more delicate and fragrant than their successors—have already gladdened the heart of the true lover of the beautiful in nature. Work however, is by no means over with, but it is now rather a pleasure than a task, for the eye is daily met by new developments of beauty.

Annuals may still be sown for late blooming. If the weather is very dry, the spot may be shaded until the seeds start. It is a good plan to lay a board over the surface, which should be removed as soon as the plants show themselves above ground.

Bulbs.—The early flowering kinds should not be lifted too early, as the bulbs should have time to ripen. When the foliage is quite dead, take them up, place in the shade where they will dry, then remove the tops and wrap in paper, taking care that each variety is properly labeled.

Carnations.—As they come into flower, the stalks should be tied up to neat stakes. The bloom of choice sorts may be prolonged by shading in mid-day. Propagate by layering or by putting out cuttings, which should be shaded, until well started.

Climbers.—Keep Wistarias, Bignonias, and other woody climbers within bounds. Layer if it is desirable to multiply. It is not too late to cover unsightly objects with herbaceous climbers. Maurandia, Lophospermum, and Cobæa, are suitable; but they start very slowly from the seed, and it is best to procure plants at the green-house. The finer varieties of the Morning Glory grow rapidly, and nothing can be more beautiful. Plant the different sorts separately and, if it is desired to keep seed distinct, keep the varieties from running together.

Dahlias.—Plant from the first to the middle of the month, and allow but one shoot to a root. Furnish stakes as soon as the plants require it.

Evergreens.—As noted in an article on another page, these may be set the first of this month.

Geraniums.—Plant out and cut back to prevent running up out of shape. To show well, they should be kept in a rounded and compact form.

Gladioluses.—As soon as the flower stems appear they should be tied to neat stakes.

Grass Edgings.—Use the edging knife, or a spade ground sharp, to keep the grass from spreading into the beds or walks. Keep grass closely trimmed.

Gravel-Walks.—Add gravel where needed. Keep down weeds as fast as they appear. The frequent use of the scuffle hoe, rake, and roller, will keep the walks in good order.

Hedges.—Young hedges should be cut back severely in order to get a good base. Clip the established ones as often as the new growth requires it.

Insects.—See general remarks under Kitchen Garden, and Orchard and Nursery. Syringe, or use the garden engine to throw water or soap-suds. A portable engine called the Aquarius is very convenient and effective. All applications should be made to the under as well as the upper side of the leaves.

Keeping.—By this term we mean the general attention to details, without which no grounds can be well kept. Remove all flower stalks not needed for seed, as soon as they are out of bloom. Take up all diseased plants. Rake off those flowers which drop readily. Tie up shrubs and all other plants which need it. Remove stakes no longer required. In short, do every necessary thing just at the right time, and in the best manner, and let the whole grounds bear constant testimony to the care and neatness of those having them in charge.

Lawns.—To have a perfect lawn, the grass must

be frequently cut. This is generally done with the scythe; there are machines which do the work well, but as the makers of them do not advertise, we do not know where they are to be had. The English makers advertise a number of patterns. The turf should not be allowed to grow close to the trees, but should be cut in a true and a well defined circle from 3 to 6 feet in diameter, according to the size of the tree. Keep this free of weeds.

Roses.—If restricted to one flower, probably the choice of the majority would be the rose. The Remontants and Hybrid Perpetuals are replacing the older sorts, and the running kinds are among the most popular climbers. Their beauty is not to be enjoyed without labor as they are much preyed upon by insects. The rose bugs should be shaken off early in the morning and destroyed or picked by hand, and the slugs, which soon destroy the leaves, should be treated to a solution of 1 lb. of whale oil soap, to 8 gallons of water. As soon as the Remontants have flowered, they should be headed back to induce Fall blooming. A much finer show of late flowers, if these are desired, may be secured by sacrificing the Spring bloom altogether.

Transplanting.—Many of the annuals will need to be transplanted. Give Asters, Balsams, Zinnias, and other strong growers ample room to develop themselves; single specimens of these are much finer than when grown in masses. Some of the tender plants will need shading for a few days.

Verbenas may still be put out. Peg down the branches so as to make a showy dense mass.

Water.—Except newly transplanted things, it is not often necessary to water. When it is applied, the surface soil should be removed and replaced after the watering. This will prevent the earth from caking, as it often does after surface watering.

Box Edging.—Last month was the proper time for making new and trimming old edgings, but it may be done successfully, early the present month.

Petunias.—Put out rooted plants and transplant any seedlings ready. Give plenty of room.

Heliotropes.—These are usually put out too early. They need settled weather. If the plant has drawn up, it should be cut back, to form a compact growth.

Vinca.—This old fashioned plant, known as Periwinkle, and sometimes as "Myrtle," has some very pretty varieties with variegated foliage, which seem to be hardy. They are fine for vases and baskets.

Green and Hot-Houses.

A large majority of the plants are now out of doors, either turned out into the borders, or placed where they will ornament the grounds. The tropical plants are still kept in the house, as well as other delicate things. Let whatever is left in the houses be tastefully arranged, in order to avoid the desolate and rubbishy look that most green-houses present during Summer. Give plenty of air.

Camellias should be placed where they will have partial shade. Cut back to give the plant a proper shape and see that insect pests are destroyed.

Cuttings.—A stock of Geraniums, Fuchsias, Chrysanthemums, Heliotropes, etc., should be propagated to furnish plants for winter blooming.

Grapes.—When the fruit is ripening the syringing overhead should be discontinued. Thin out the late crops. Bearing shoots should be shortened to three leaves beyond the bunches and all unnecessary shoots pinched off. Air freely and water as needed.

Inarch those hard wooded plants which do not strike readily from cuttings, nor from layers.

Oranges, Lemons, etc., may be budded this month.

Potting.—Rapidly growing plants need more pot room and should be shifted to larger sized pots. Potting soil should be always at hand. Sods from an old pasture piled up and allowed to decay make an excellent compost, this mixed with sand as may be required, will answer for the majority of plants.

Seedlings started in the green-house may be potted off or set out in the grounds as fast as ready.

Verbenas.—A stock for winter flowering should be propagated from cuttings. They strike easily.

Water.—Plants in small pots will dry out rapidly; give a supply of water as needed. See that the pots out of doors have thorough drainage, or the earth in them will remain soaked after heavy rains.

Apiary in June.

June is the swarming month in the Apiary, and at least one new colony should be expected from each old stock. A hive from which no swarm issues should be examined. If they have refused to leave for want of a queen, they will usually be found weak, when it is best to drive them out and unite them with some other stock. If the colony is strong, a new queen, or a cell containing a queen, can be introduced from some other hive. If a hive has failed to swarm from diseased brood, drive them into an empty hive to commence anew...

When two swarms issue at the same time, they are apt to settle together. To prevent this, sprinkle the bees of one hive with water, as they are about to start, which may be usually discovered by the commotion about the entrance of the hive a few moments before flying. The sprinkling will delay them until the first swarm can be hived... The first issue from a hive is usually large enough for a good colony, the second half as large, the third a quarter, consequently two of the second, or four of the third will be needed to make a swarm equal to the first. If second swarms issue late in the month it is advisable to make one strong stock by uniting two. It can be readily done within a day or two after issuing. It has been proposed to prevent the issuing of a second swarm by returning the old queen to the hive. This would only be likely to end in one of the following results: The queen might destroy all the royal cells, and go on laying eggs for three or four weeks, until another swarm had matured, when she would issue, leading out a second swarm. Or she might leave the royal cells undisturbed, and issue the next day, taking with her a small swarm. Or she might entirely disappear without being heard of again; at any rate her presence would not be likely to prevent a second swarm. Prevention can be accomplished in the movable frame hive, by cutting out the queen cells after the first swarm has issued and after the young queen has taken her place, and not allowing any such to be perfected... If a second swarm can not be well disposed of otherwise, return it to the old stock. Hive it first, carry it near the old stand, and let it remain until next morning, when all the queens but one will usually be destroyed, as well as the supernumeraries in the parent hive. Shake out the swarm, and find and secure the queen; then put a few bees at the entrance, with something on which the rest may creep there, and they will all readily enter... All new swarms should be kept shaded during the middle of the day... When bees cluster in a crowd at the outside of the hive, it is time to add boxes to receive surplus honey. If the honey is intended for home consumption, a wood box will be sufficient; for marketing, those with glass sides are preferable. They should be not more than five inches deep. The bees will work in them more readily if pieces of nice white comb are placed in the top. They can be fastened by dipping one edge in melted beeswax, and applying before it cools. Old colonies should be induced to begin in the boxes before they swarm, as the bees will be more likely to finish up the work, than to begin after swarming, especially if the colony be not very strong. Remove the boxes as soon as filled. It is not usually advisable to put on boxes immediately after hiving; the bees are likely to rear brood and store bee-bread in them. It is safe to put them on after the swarm has been hived three or four days.

TO KEEP RABBITS FROM GNAWING TREES.—John M. Lacey, Mahaska, Iowa, writes that after trying other expedients, he has for the last two years given the trees a coat of soap and sulphur, and that they have been unharmed by the rabbits. He says he saw the hint in the *Agriculturist*, and thinks we should republish it annually.

A Curculio Talk.

At the Fruit Grower's Meeting, held May 7th, the curculio question was brought up and discussed at length. Some members took the ground that the plum crop was the least valuable one, and might be left to this insect, while others complained that they could not raise apples in seasons of scarcity owing to the depredations of the curculio. Dr. Trimble, of New-Jersey, who has made this insect a study for years, thought it was cowardly to give up any of our fruits to their insect enemies. He showed a vial containing 100 curculios (bred from apples), another vial with 100 pea bugs, and a third vial having 100 grains of buckwheat, to show that the three were nearly of the same size. After pronouncing against the various solutions and powders recommended for their extinction, all of which had proved valueless to him, he said the only reliable method was to turn the hogs into the apple and plum orchards, to eat up the punctured fruit as it fell from the trees, or pick it up by hand, and destroy it. This disposes of the embryo insect, which would be troublesome the next year. But when the curculio comes, his plan is to jar it from the trees upon sheets, using care not to start the bark. The hand is sufficient to jar small trees.

He has a stout sheet made, 12 feet square, with a pole attached to one side, and a slit made in the opposite side to the centre. Two short poles are also fastened to the side where the slit is made, to stiffen the cloth. The sheet is then taken by two boys, who place it under the tree with the trunk in the centre, when a third person hits the tree two or three raps and the lads soon gather up what insects fall, and march off to the next tree. The orchard is soon gone over in this way, and in clear weather the process must be followed up each day or oftener if the insects are found at work—in cold or rainy weather they do not trouble the trees.

The Dr. has satisfactorily proved that the perfect insect or beetle emerges from the ground in August, or four to six weeks after it enters the earth in the larva state, and spends the winter in crevices of bark, under shingles, and between boards of old buildings, etc., and is all ready to attack the plum and apricot as soon as the fruit sets. This is usually about the 18th of May, and they do most of their damage between that time and the 1st of June. Hogs must do the work in the apple orchards, as large trees can not be jarred. Cherries are often stung and ripen prematurely. Birds destroy a great many of them, as they often take the early cherries as much for worms found in them, as for the cherries themselves.

If any one doubts that the curculio attacks the apple, let him gather the fallen fruit the last of June, or early in July and put it in a barrel with several inches of earth. Spread gauze or millinet over the barrel and the curculios will be secured when they attempt to leave the earth.

Strawberry Exhibition.

AT THE
Office of the American Agriculturist

The Proprietor of the *Agriculturist* invites Strawberry Growers, of this vicinity and elsewhere, to make an exhibition of their choice fruit on Thursday and Friday, June 18th and 19th,* at the *American Agriculturist* Office; and to give zest to the exhibition, he offers the following

PRIZES:

A—For best 25 approved varieties (one quart each)...	\$7
B—Second prize.....	5
C—Third prize.....	3
D—For best dish of market berries (two quarts of one variety.—It will be very desirable to show plants with fruit in addition).....	3
E—For second and third best do. do.....	\$2, \$1
F—For largest three berries of one variety, (weight and size both being considered).....	2
G—For best New Seedling not before exhibited.....	5
H—For Second Best Seedling not before exhibited.....	2
I—For best flavored Strawberries (one quart).....	2
J—For best quart of White Strawberries.....	2
K—For best quart Everbearing.....	2

No sample can compete for more than one prize. The berries to come in competition for the premiums must be upon the tables as early as 11 A. M. on Thursday June 18th, and each specimen must be correctly labeled. The Awarding Committee will attend to their duties at 12 M.—The exhibition will not open to the public until 2 P. M. When the premiums are awarded, the names, residence, and places of business of the exhibitors will be put upon the specimens, and the prize samples designated.

No Fruit exhibited will be removed before Friday evening without special permit.

Containing a great variety of items, including many good hints and suggestions which we give here in small type and condensed form, for want of space elsewhere.

The Premiums Close in July.—That there may be no disappointment, we repeat that all premiums of every kind, general and special, will close in July, excepting only the new Barometer Premium, and the Wringing Machine No. 2; these will continue open to August 31. For special Premiums see page 192. For general Premiums see page 155, last month. It is not at all certain that we shall offer any premiums in the future; the price of paper, etc., will decide that matter.

To Correspondents.—The paper is finished up about the 20th of each month preceding that for which it is issued, and nearly all reading matter must be in the hands of the printer by the 15th, or before. We have numerous letters asking us to reply in "next month's paper," which come too late for us to do so. To many of these queries the answer would be too late if published on the following month. For this reason many correspondents remain unanswered. To others we can not reply without taking time for observation and investigation; while some we can not answer at all; and still others are deferred for want of room.

The Best Barometer Cheap.—We invite particular attention to the Special Barometer premiums on page 192. The publisher is of course interested in the business part of the arrangement, for he is making an effort to raise the circulation of this journal to the highest possible point at the present time, in order to meet the very greatly increased expenses, without raising the terms. But aside from this, the barometer offered is not only an excellent one, but it is a thing that it will pay to have in every house. If it promote the better gathering of a crop in only a single instance, as it will be quite likely to do, it will pay well for its cost. The annual interest on \$8 or \$12, is only 50 to 80 cents a year, and even as a useful ornament, the barometer would be worth this much, to say nothing of its value as a weather guide. The terms upon which it is now offered are special, and can not be continued beyond the period named. The small number of subscribers required, can be readily obtained in almost every neighborhood; the paper will be well worth its cost to the subscribers, and the barometer will repay the trouble taken by those who secure them. Even should a person himself subscribe for half of the required copies and present them to his friends or neighbors, he would still secure the Barometer cheaply. We are quite sure the instrument offered will give entire satisfaction, and be found a paying investment. The safe delivery guaranteed is a special inducement.

Come to the Strawberry Show.—From present appearances the display of strawberries at the *Agriculturist* Office, June 18 and 19, will be well worth visiting. The plants have set a good crop of fruit, which with favorable weather will be ready at the appointed time, notwithstanding the late Spring. On the first day the doors will be closed to all but the Judges, until 2 o'clock P. M., after which the public will freely be invited to feast (their eyes) upon the magnificent display anticipated. See announcement on page 164. The Committee of Award was announced last month, page 126. This Committee is one of the most competent that could be selected from the whole country, and their judgment will be valuable. No one to whom there can be the least reasonable objection will act upon the Committee.

"Alkekengi."—A friend in Philadelphia has sent us a Boston circular setting forth in glowing terms his "new and beautiful fruit," under the above name. From the description we conclude it to be the Winter Cherry (*Physalis viscosa*). It is a very good thing for preserves, and we have distributed the seeds freely for several years. The *Physalis Alkekengi*, from the South of Europe is a larger, better fruit, but unless started early in the green-house, does not always ripen. The seed, if desirable, can be obtained cheaply at the large seed stores.

"Ice Cream in Four Minutes."—So reads the advertisement of Torrey's "Arctic Freezer," and it is not far from the truth. The manufacturer brought some ready flavored cream, salt, and pounded ice to the *Agriculturist* Office in one of the hot days of May, and commenced operations against time. According to our "chronometer," in 4 minutes the cream was pretty stiff with cold; in 5 minutes it was solid; in 7½ minutes it was beat to a smooth paste as good as the best

that ever was made—and in 12½ minutes it was all gone,—by the aid of our whole office force, and a crowd of visitors—invited and uninvited.—So much for the time. Mr. Torrey's freezer is a good one, the best we have seen; it is cheap, and the apparatus for stirring the cream, and the freezing mixture at the same time, greatly facilitates the freezing.—Wherever ice is accessible, farmers who have the genuine cream, or the rich milk and fresh eggs, can have such (nice) cream as is seldom seen by city dwellers. A quart of cream will make a far more delicious dessert for dinner than the best pie or pudding; will cost less money and labor, and be far more healthful on the top of a hearty dinner of meats and vegetables.

What a Woman Can Do.—J. B. Bardwell, Worcester Co., Mass., writes to the *Agriculturist* that an unmarried woman of that place, now over 80 years old, a few years since bought a farm for \$5,300, and recently added to it a pasture lot costing \$500 more. She had accumulated the whole by doing housework at \$1.50 per week, and putting her savings at interest. She formerly let the farm to tenants, but not liking their doings, last year she assumed the management, and with the help of one man carried on the business. She kept sixteen cows, attended personally to the dairy, and attended her own housework, besides doing the marketing, etc. A large class of young men who are idly "waiting for something to turn up," should take lessons from this old lady.

Native Fibres.—We have received from Justin S. Lewis, Franklin Co., Kansas, the fibre of a kind of nettle; from M. Taylor, Alleghany Co., Pa., a piece of cord from the fibre of a species of Milkweed probably; and from J. Howells, Wood Co., Ohio, a sample of the fibre of what is probably the Indian Hemp.

A Watering Apparatus.—"W. H. W.," communicates the following convenient plan for watering seed beds or plants generally. "Take a hogshead or other large water tight cask, and set it in a wagon upon the head, bore a hole in the upper head for inserting a funnel by which to fill it from the brook or river. Have, near the bottom of the cask on the side, a stop-cock to which a rubber hose is to be attached by a coupling, with a sprinkler at the other end. Have the hose of any desirable length and the head of water in the cask will force the water through the hose and out of the sprinkler which may be directed to any desired point."

Seeding Stony Land.—"Z." Bolivar, Md. We should advise to go over land too stony to be plowed, with a heavy harrow, sow grass seed, timothy on low land, and then top-dress with fine manure. It is rather late for the operation the present season. The sun would be likely to kill out the young grass plants.

Fruit of Pistillate Strawberries.—F. Thomas Reilly, Ottawa Co., O. The fruit of pistillate strawberries would be but little influenced by the variety of staminate used to fertilize them. The seed would partake of the character of both of the parent plants.

Trouble with Grapes.—J. S. B., Keyport, N. J. You say that your ground "is very wet all winter and spring." This is a sufficient reason for the failure of any grape. Drain the ground. Your variety, the Isabella, is very apt to wither during the summer.

Puddling Trees.—We do not believe in the practice, except where the roots are necessarily exposed for some time before planting. In this case a coating of mud will protect them somewhat, but we would always wash it off before planting out, that the fine rootlets may be spread out rather than lie cramped and matted together, as puddling leaves them.

Plum Trees.—G. S. Tinker, Portage Co., O. Your fruit is probably attacked by curculio. See p. 164.

The Tribune's Strawberries.—Though the advertisement of these plants comes in competition with one of our special premiums, we cheerfully admit it. We believe in strawberries for the million. No fruit is more readily and quickly grown, and nothing is better adapted to the circumstances of the masses. Not a few journals formerly sneered at the seed and plant distribution of the *Agriculturist*, but there are millions of plots of beautiful flowers and of other plants now growing in this country, the original seed of which came through our general and premium seed distributions. Probably nine-tenths of the important sorghum crop now being grown is derived from the twenty to thirty thousand parcels of seed distributed all over the country, a few years since, from the office of the *American Agriculturist*. Let the *Tribune*, let any other journal in the land,

take up and carry out the plan we have so long followed; it will help beautify the garden, and supply the tables with luscious home-grown fruit. In the meantime we shall not wholly retire from the field; see our special strawberry premium on page 192.

Maple Syrup for Strawberries and Wine.—H. P. Bratt, Ozaukee Co., Wis. Maple syrup will probably impart a little of its own flavor to these, but as the flavor is generally liked, that may not be an objection. If made clean and dry, it ought to have the same preserving effect as its kindred cane sugar. It would be well to try it on a moderate scale at first; and please report the results to the *American Agriculturist*.

Crops in Salem Co., N. J.—A. W. Hillman writes that sweet potatoes are largely planted in that county, farmers often devoting from 6 to 20 acres to that crop, and that this year more than usual will be planted, on account of the probable short crop at the South. Small lots of flax, tobacco, sorghum, and cotton, will be grown. The desired information given in May No.

Book for Dairymen.—A. H. Miner, Orange Co., N. Y. Flint's *Milch Cows and Dairy Farming* contains the information you need as to breeds of cows, and their general management. It comprises much practical matter on dairying, and is well worth the price, \$1.50, to every one engaged in the business. See page 186.

Domestic Silk.—L. H. Davis, Suffolk Co., N. Y., sends a skein of very nice sewing silk of his own manufacture. We know not where to get eggs. Who does?

Plants for Names.—"D." Makanda, Ill. The plant enclosed is *Collinsia verna*, one of our prettiest Spring flowers, and worth cultivating. The "May Apple" you describe, is *Azalea nudiflora*, and the portion eaten is a sort of excrescence, or rather monstrosity of the flower, supposed to be produced by insects, though the fact is not well established. Your other plant is probably *Calystegia pubescens*; is very pretty, but its roots spread so rapidly that it becomes a nuisance. Lula S. Lauber, Lancaster Co., Pa. The plant is *Epigaea repens*—known as Trailing Arbutus and May Flower. Nothing is more beautiful or fragrant, but it is difficult to cultivate. Must have a rather peaty and moist soil, and be shaded. H. B. Comstock, Cortland Co., N. Y. We do not recognize the very pretty leaf; send flowers; no seed came. You are right: a plant is worth double with a correct name.

Cauliflowers.—"C. A. W." Hudson, N. J., asks why the cauliflowers grow up into long sprouts, when not immediately cut. The head of the cauliflower is a mass of undeveloped flower stalks and buds. When the season is long, these go on and develop and throw up branches to flower and bear seed.

Craig Microscope.—To Many Inquirers.—For looking at very small objects, such as the dust upon a butterfly's wing, starch grains, etc., this does remarkably well for so cheap an instrument. For examining seeds, flowers and such comparatively large objects it will not answer at all, as the focus is very short. For these purposes a common pocket glass, such as is generally sold by opticians is better.

Flower Pots.—Eleanor Rielson, Junenew Co., Wis. The hole at the bottom of the flower pot is for the purpose of securing drainage. Were it not for this, the earth might become too wet for the health of the roots. The proper amount of moisture is that which the earth will hold when the excess can drain off. A few pieces of broken pots, or bricks, or small stones, should be at the bottom of the pot, before filling with earth.

German Stocks.—C. A. Nelson. These being annuals cannot be kept through the Winter by covering. They must be grown from seed each Spring.

Squirrels Carnivorous.—J. R. Pierson, Susquehanna Co., Pa., alluding to an item under this head, on page 262 last Vol., says he shot a red squirrel in the very act of making a meal of some half grown robins.

Cauliflowers.—"N." Ravenswood. See page 146, last month. Your seed is probably unreliable.

Use for Sawdust.—J. K. Niest, Stark Co., Ohio. Sawdust is valuable to compost with yard manure, or to apply alone to lighten heavy clay lands. It is excellent as a mulch for fruit trees, vines, etc., and may be used advantageously for this purpose during drouth.

Horse Cleaner.—P. S. Brokaw, of Somerset Co., N. J., objects to using currycomb, or brush, or the implement described in *May Agriculturist* (page 141) for removing mud from horses, because it is unpleasant to be so near the animal while using them. He recommends the stump of a worn out broom, with which the work can be equally well done and at arms' length.

A Cow Nursing Pigs.—B. Beaver, Washington Co., R. I., writes that a farrow cow owned by him was seen on several occasions lying in the barn yard, with two of a litter of pigs in the same enclosure busily drawing supplies of milk from her well furnished bag. The cow seemed in rather enjoy the novel experiment.

Hungarian Grass for Sheep.—Luther Allen, Randolph Co., Ind., requests those who have tried feeding sheep with Hungarian grass to give the results.

Book on Sheep.—C. T. Wilson, Washington Co., Wis. We know of no better work on sheep raising than "Randall's Sheep Husbandry," price \$1.25. We can forward it by mail, post-paid, at this price.

Choice Eggs.—G. W. Cook, L. I. Poultry fanciers sell eggs of their stock, but there is great risk in transporting them. Jarring often destroys vitality. If packed at least carefully, partial success may be realized.

Sex of Eggs.—M. Genin, in a communication addressed to the French Academy, states that eggs which contain male chicks, have wrinkles on the smaller end, while those which are to bring forth females are smooth. We should like to hear results of observations and experiments to discover the truth or falsity of the matter.

Good Maple Sugar—A Hint.—The cake of Maple Sugar reported on our Exhibition Tables last month, from L. Wolcott, Croton, N. Y., has since been tested, and proved unusually excellent in flavor as well as in internal appearance. The lesson to be learned is, that the secret of making such sugar is expressed in one word—*cleanliness*. There is no doubt that pure white, well flavored maple sugar can be made by catching the sap in clean covered vessels, and boiling it down in clean vessels shielded from falling smoke, ashes, leaves, or other filth. The nearer we can approach to this point, the nearer perfect will be the sugar. Those who have permanent sugar groves would undoubtedly find it a paying investment to secure a set of good covered buckets with an arrangement by hook or staple to suspend them on nails or spikes driven into the tree.

Blackbirds.—A. A. Stewart, Logan Co., O., speaks in behalf of these persecuted birds. He does not find them pulling corn or molesting the young of other birds. "They follow the plow and pick out large numbers of worms and grubs, and are the farmer's best friends. Not so the crow and blue jay, which devour the eggs or nestlings of other birds. True, the crow destroys large numbers of insects, and claims some leniency, but the sly jay merits shooting at sight."

Prolific Bees.—Thomas Thompson, of Wausau Co., Wis., says he purchased a swarm of bees last Spring, and during the Summer took 8 swarms from it.

The Asparagus Beetle.—Dr. Asa Fitch, stated at a recent meeting of the Executive Committee of the N. Y. State Agricultural Society, that the Asparagus Beetle, which has recently proved very destructive to this vegetable on Long Island, is readily devoured by chickens. As they do not injure the crop, they may be made serviceable in extirpating the pest.—Worth trying.

To Keep Striped Bugs from Squashes.—In sending some squash seeds to the *Agriculturist* Office for trial, an Illinois correspondent says he keeps the striped bugs from his vines by watering with filthy suds from the wash room, and then dusting with coal ashes. This is repeated as often as the ashes are washed off, and the squashes are not injured by the application, or by bugs. In the absence of coal ashes, dry soil may be used.

"Rooting" out Grubs.—A writer in the Country Gentleman says that, having lost a corn crop by grub worms he turned in the hogs, and they instinctively sought out the grubs, rooting them up and devouring them. On another occasion, an old pasture was badly infested with this worm, and the hogs being turned in after haying, they rooted up the worms wherever the wilted grass showed their presence.—Such a thing might occur on very light soil, but we very much doubt

whether as a general rule hogs would root after grubs without finding some other food inducement in the soil.

To Repel Insects.—Charles H. Snow, Baltimore Co., Md., writes that plaster of Paris, mixed with spirits of turpentine, one pint to a bushel, and sown upon cabbages, turnips, melons, etc., repels insects. The plaster is a good preventive; the turpentine may be an addition.

Dissolved Bones.—"G. W. C.," Queens Co., L. I., we have already stated that muck, or in its absence good soil, should be used to dry the wet compound.

Stone Gathering Machine.—C. Bonnell, Wyoming Co., Pa., inquires where a machine for gathering loose stones from the field by horse power may be obtained. We have seen descriptions of such an apparatus, but do not know if it is manufactured at present. The inventor or proprietor should advertise it, if good.

Tree Chopping Machine.—Julius Meyer, Potter Co., Pa. We have not seen this apparatus, which was patented in 1859. It has not been brought before the public, and we judge is not of great value, or its merits would have been made more widely known.

Prospective Demand for Sorgho Syrup.—In a communication to the *Sorgho Journal*, Isaac A. Hedges gives extracts from a letter written by Belcher, the great sugar refiner of Chicago, Ill., offering to contract for *Twenty Thousand barrels* of fair to good raw sorgho syrup, at *forty cents per gallon*, for refining. This offer has doubtless influenced many to plant largely, under a guaranty of a good price and a sure market.

Manual of Flax Culture.—Under this title D. D. T. Moore, of the Rural New-Yorker, has issued a handsomely printed, illustrated pamphlet of 48 pages, containing considerable information of interest to flax growers. There is less detail of experience by practical men than could be wished, but the work contains hints and suggestions fully worth the low price (25 cents, post-paid) at which it is issued. We will have it to supply.

Black Walnut Posts.—"J. S. S." Mansfield, Ohio, inquires how long black walnut posts will last in the ground. He reports a case in which black walnut and oak posts were set together, and the walnut are sound while the oak are completely decayed; the walnut posts are likely to outlast a new set of oak posts.

Scientific Questions. — A Weekly Journal wanted.—B. M. French, Montgomery Co., Pa., and a number of others. It would be interesting to a limited class of intelligent readers, to discuss the theories respecting the action of ammonia and other compound and simple elements, and a thousand other questions, and when enough readers demand and will support a large weekly Journal devoted to the science as well as the practice of Agriculture, we shall be glad to publish such an one. It would pay the farmers of the country to support at this metropolis a journal that could not be issued at less than \$3 to \$5 a year, one giving extensive reports of the grain and other Agricultural markets, and of Agricultural intelligence generally. But the people are not ready for it yet. We are watching the indications, and as soon as there is a reasonable prospect that such a journal will be supported, we promise that it shall be forthcoming. Until then we must confine ourselves to a monthly at a low price, such as will meet the practical wants, and the views of the public mind as it now is.

Grapes on a Rock Heap.—A New Hampshire reader of the *Agriculturist* writes that he finds grapes do the best when running over a heap of rocks. The rocks absorb the heat during the day, and radiate it gradually during the night, keeping up a gentle warmth.

Making Raisins.—H. A. S., will find directions on page 325, Nov. *Agriculturist*, 1861. Only sweet varieties of grapes can be used; no sugar required.

Standard Trees — Dwarf Trees — How Produced?—In answer to inquiries from several readers of the *American Agriculturist* we explain: *Full Standard* trees are those growing on roots of the same variety. These are usually allowed to grow full size, and generally with trunks trimmed five to six feet high. *Half Standards* are those cut in somewhat, in the limbs, and are allowed to branch two to three feet from the ground. *Dwarfs* are usually worked on a small stock of some slow growing variety; and are usually trimmed to a pyramidal shape. Thus to produce dwarf pear trees, they are grafted on quince roots

(usually the Angers quince); sometimes on the thorn. Apple trees are dwarfed by grafting upon the Doucain stock, which is a small-growing species of apple, that naturally produces small, sweet apples. The Cherry tree is dwarfed by grafting upon the Mahaleb cherry, a naturally dwarf stock. Peach trees are given a dwarf shape, not by grafting, but by cutting in, planting in pots, etc. Ornamental trees are dwarfed by grafting the finer large varieties upon roots of some other variety of the same species.

To Resuscitate Dry Trees.—It not unfrequently happens that trees imported from abroad, and even those sent from nurseries a long way over-land, are quite dry and shriveled when the burlies are opened, and some persons would throw them away at once as worthless. Two subscribers to the *Agriculturist* inform us that they received some fruit trees in this condition, and at once planted out the freshest of them and buried the others, *root and branch*, in the earth. Those planted out when received, mostly died, while the others, after remaining buried for a week, were set out and nearly all lived. They were found to be restored to freshness when taken from the trench in which they were covered.

Ground Cherry.—R. A. Young, Allegheny Co., Pa. The Ground Cherry fruits the same year from the seed; it is worth cultivating for preserves. Earth Almonds or Chufas are not the same as the Ground Nut. The tubers are planted. Both can be had at the seed-stores.

Good Strawberry Mulch.—Z. Breed, Hillsboro Co., N. H., who has raised strawberries for market ten years, writes that he uses muck for a mulch between strawberry rows, with chaff or chopped straw around the plants to keep the berries from getting soiled. Muck absorbs and retains heat, thus warming the soil, and it also keeps moist for a long time.

Scorzonera is the name of the seed sent for identification, by S. A. Green, Pierce Co., Wis. It is cultivated and used the same as salsify (vegetable oyster) which it resembles, but it grows to a larger size, and the root is dark colored instead of white like the salsify.

Fine Camellias.—Our exhibition tables were gay, a short time ago, with specimens of this favorite flower, from Mr. Chorlton, the well-known horticulturist of Staten Island. The varieties were: Dunlop's White; Speciosa; Alba plena; Lowii; Myrtiflora; Rubescens; Marchioness of Exeter; Binneyi; Formosa; Imbricata; Prince Albert; Donklearii; Sherwoodii; Chalmerii perfecta; Pæoniiflora; Abby Wilder; and Floyli.

Holocantha.—"J. H. P. G.," Ill. This is a native of the barren plains of Northern Mexico. It would not be likely to flourish, even if you could obtain it. We have seen it in its wild state, and an ugly object it is.

A Desirable Aquatic Plant.—We have seen in some grounds near Boston, a very free-growing and highly ornamental plant for artificial ponds: the *Limncharis Humboldtii*. It has fine dark-green foliage, and bears an abundance of large lemon-yellow flowers. We grew it last year very successfully in a tub sunk in the border. The plant will not stand the Winter, and enough should be kept over in the house or cellar to continue the stock. Planted in a basket of peaty earth, and set in shallow water, it soon becomes established, and spreads rapidly. It is a fine plant for the aquarium. Sold by B. Greenwood, 394 Broadway, New-York City.

Can't do Without It.—"The following pithy letter was received from an old subscriber in Wallingford, Conn.: "I for *Agriculturist* for 1863—can't do without it—'Children cry for it'—neighbors borrow it—Refer to it weekly, sometimes daily—Tells me 'how to do it,' and 'how not to do it'—vive l' *Agriculturist*, and its Editors, and Tim Bunker, Esq.—You should see my pear trees—my roses—my compost heap! all on account of the *American Agriculturist*—keeps me bewitched about trees and fruits and flowers"—and all for a dollar year."

Worcester's Dictionary—Postage.—Miss Elizabeth Bewman, Lenema Co., Cal. This book weighs 10 lbs., and, if pre-paid, costs \$1.60 postage within 3,000 miles, or \$3.20 to California and Oregon. The Express Co., charges us \$5.00 each, on the dictionary to San Francisco. It is therefore cheapest to send by mail.

Fancy Printing.—J. J. Herst, Pa. In fancy printing or printing in colors, the work generally goes through the press as many times as there are colors. Sometimes the compound colors are produced by printing one color over another, as purple, by red over blue, etc.

How often Should Mares Breed?

—E. S. Phelps, Bureau Co., Ill. A healthy mare of strong constitution may safely bear a colt annually for several successive years, but it is exhaustive of strength, and is usually best to intermit every third year, and in many cases every other year.

Cure for Scratches on Horses.—T.

Lashbaugh, Laporte Co., Ind., writes that he has never failed in curing scratches in horses, by applying melted tar to the affected parts. It should be rubbed in well, and the hair smoothed down over it.

The Currycomb in Summer.—Farm-

er's Boy, inquires whether the currycomb and brush are necessary for horses in warm weather. Certainly, even more than in Winter. Remove dust and perspiration gathering under the hair to keep the skin healthy.

Kicking Mules.—M. B. Turner, Lee Co.,

Iowa. Mules may be cured of kicking, and otherwise made gentle, by the application of Rarey's system of taming. A full description of his method is contained in Herbert's Hints to Horsekeepers.

Book for Horsekeepers.—C. T. Vin-

cent, Hartford Co., Conn. We know of no better work for general directions and sound every-day practical suggestions on the management of the horse, than Herbert's Hints to Horsekeepers. We can send it post-paid, by mail, for \$1.25.

To Prevent Hens Sitting.—Christian

Paltz, Buffalo Co., Wis. Hens may sometimes be cured of a propensity to sit by dousing them with cold water.

How Many Sheep to the Acre?—S.

S. Wiest, Lancaster Co., Pa. From three to nine sheep per acre of grass land may be kept, according to its quality and the kind of sheep. It is generally reckoned that 8 Merinos consume about as much as an ordinary cow.

Corn and Wool.—"J. M.," Logan Co.,

Ohio, inquires whether it be true that every pound of corn fed to sheep will add one ounce to the growth of wool. It might in some cases, but the statement appears to be rather a loose one. Sheep breeders are interested, and it would be instructive to hear the results of careful experiments made to ascertain the value of corn for this purpose.

A Good Hog.—Wm. T. Russell, Ulster Co.,

N. Y., writes to the *Agriculturist* that in August last he commenced feeding a shote weighing 100 lbs. live weight. For two weeks his provender was best quality wheat bran and milk; from that time to December 2d, he received all the Indian meal he would eat, with a very small quantity of milk. He was fed just 107 days, and gained 257 lbs. in that time. (2½ lbs. per day—less 10½ lbs. on the whole.)

A Patent Hog Ring.—Daniel Brown,

Marshall Co., Ill., sent to the *Agriculturist* office some time since, a newly invented hog ring for which he has received a patent. It consists of a spiral coil of wire forming a spring, which rests in front of the animal's snout; the two ends of the wire are bent so as to enter the nostrils and clasp the membrane within, where they are held by the spring. It is easily applied, and Mr. B. says was found very efficient last Summer in a herd of one hundred swine.

Sulphur for Lice.—Several correspondents

have written to the *Agriculturist*, that sulphur fed to cattle, will rid them of lice. One who says he has used the remedy successfully in a number of cases, directs "to give two tablespoonfuls in a quart of meal to each animal, to be given daily until cured." Sulphur is used in the human system as a gentle laxative, and for several diseases of the skin. That it escapes from the surface of the body, is shown by the odor, and by its blackening silver articles in the pockets, and on this account, it is not unlikely that it may affect insects on the bodies of animals. A few doses may, in some instances, by its cathartic effect improve the health of the animal, and thus prove effective against lice, which are chiefly found upon debilitated or sickly animals. The common sulphur powder frequently produces griping when used as human medicine, to counteract which it is mixed with ¼ to ½ its bulk of calcined magnesias, or cream of tartar, and this mixture would probably be the best to give to animals.

Defective Teats in Cows.—Abraham

Williamson, Hendricks Co., Ind., inquires whether the half of a cow's bag which has from some injury ceased to give milk, will yield it again, at the time of her calv-

ing. Probably not, although it may depend somewhat on the nature of the injury. We have never known a defective teat to be thus restored.

Lizards in a Spring.—E. Day, Kingston,

Ulster Co., N. Y. We would not advise to destroy lizards. They are as harmless as fish, and as they feed mainly upon insects, they help to keep the water pure.

Ants.—H. L. Moss, Minnesota, wishes to know

how to kill ants in his flower garden. He has tried hot water, sulphur, ashes, salt, carbon oil, etc., ineffectually, and so have we. Who can tell how to kill ants in the garden?

Burning the Striped Bug.—F. Thos.

Reilly, Ottawa Co., O., recommends to burn brush over the ground on which melons and other vines are to be planted, and also in the Fall, on spots which they have occupied, to destroy the larvæ of Striped Bugs and other injurious insects. This would undoubtedly kill many in the immediate locality, if the fire were large enough, but numerous others would undoubtedly come from the surrounding ground, to take their places.

Bee Queries.—A. Webster, most of your

inquiries are answered in the "Apiary" for the present month. To introduce Italian bees into a large Apiary, movable comb hives of some kind are indispensable.

Chloroforming Bees.—T. H. Mason,

Litchfield Co., Conn. This has been practised by a few parties without injurious results to the bees, but we should be fearful lest an over-dose might, in unskillful hands, destroy the swarm. A little tobacco-smoke blown into the hive will usually render the bees inoffensive.

Insects on Pine Trees.—C. A. Nelson.

The "little white fuzzy insect" described, is doubtless the Pine Blight. It mainly affects slow growing trees in poor soil. Remove it by scrubbing the bark with soap-suds.

Insects on Fruit Trees.—At a recent

Fruit-Growers' Meeting, Mr. W. S. Carpenter stated, and many members agreed with him, that he relied upon a healthy growth to keep off insects. It was his opinion that a perfectly vigorous tree would defy the attacks of the different varieties of bark-lice, while a tree set out with no more care than if it was a post, and afterward neglected, would soon be injured by them.

Insects on Roses.—H. B. Comstock, Cort-

land Co., N. Y. The color of the rose-leaf hopper is yellowish white. We can not tell the other insect from the description. The cut worm usually works near the ground, it may climb bushes but we never knew that it did.

Unseasonable Grasshoppers.—Mr.

J. H. Patterson writes that Grasshoppers appeared near St. Clairsville, O., about the 20th of March, in large numbers, and that they passed through two snow storms and continued wet and cold weather without injury.

Aphis in Australia.—A friend in that

far off land sends us a slip from an Australian paper which says, they destroy the plant lice with a decoction of an astringent bark. This completely "tans their hides." Will some of our friends try the effect of a few applications of a decoction of oak-bark, and report result?

Eggs on Apple Trees.—J. P. Funk, Md.

The specimens sent were the eggs of the Katydid.

Cementing Cellars.—"J. J. W.," Meriden,

Conn. If we had a damp cellar we should cement it even if floored with brick. See article on page 174.

Designating Grapes by Leaves and

Wood.—L. Varies, Madison Co., Ill. A person familiar with the different varieties of grapes can in many cases pick them out while growing, by examining the appearance of the leaf, color of wood, length of joints, etc., without waiting for them to ripen fruit.

Deep Planting of Vines.—C. R.

Thomas, Warwick Co., Ind., says that the Germans in his neighborhood set grape vines three feet deep in the soil, to prevent rot, and asks our opinion of the practice. If we wished to kill a vine, or put it where it would have to struggle for its life, we should put its roots three feet below the surface. The vines may survive, but it will be because they throw out roots near the surface, while those far below will soon become a decaying mass.

Prolific Grape Vine.—Amos F. Hannah,

Portage Co., Ohio, says he has an Isabella grape vine

which has been allowed to grow pretty much as it pleased, and has given good crops, with two exceptions, for 13 successive years. In 1850 it yielded 6½ measured bushels of excellent grapes. Mr. H. challenges a better result from a single vine trained according to the books. Its roots receive two or three pails of soap-suds on each washing-day, and the ground is kept mulched with decayed leaves, rotten wood, walnut shucks, etc.

Grapes in April.—Not hot-house grapes,

but Isahellas and Dianas, simply kept in the cellar, the same as apples. So reported Mr. T. W. Field, at the New-York Fruit Growers' Meeting. He saw them at Syracuse, N. Y., the 16th of April, and to appearance and taste, they were in a fine state of preservation. They were kept by the bushel, simply spread on shelves, or laid in boxes with lids at different heights on side cleats to prevent the upper clusters pressing those below.

Profitable Orchardng.—Dr. I. M.

Ward, of Essex Co., N. J., stated at one of the New-York Fruit Growers' Meetings that he always realized from \$1000 to \$1200 per annum from an orchard of 1½ acres, planted with dwarf and standard pears and apples. He lets the trees have all the soil, but plows the ground lightly in the Spring, and runs a one horse cultivator over the surface at intervals during the Summer.

Fruit the First Season.—C. D. Walters,

Worcester Co., Mass. Transplanted trees, vines, etc., should not be allowed to ripen fruit the first season, because all the strength of the plant is needed to repair the injury done to the roots by removing. Fruiting always taxes the highest energies of vegetation.

Disease in Apple Trees.—Henry Weaver

writes us that the bark of his apple trees becomes black and the trees die. Others have made the same complaint. We are not able to say, without specimens, what the disease is. As it begins with a small spot and extends, it may be some fungus. We should perhaps try cutting out the infected spot as soon as it appears.

Recognizing Fruits.—O. C. Wilson,

Perry Co., O.—Downing's Fruits and Fruit Trees of America, gives descriptions and drawings of most of the cultivated fruits, by which a person can usually recognize any named sort. It also contains thorough and reliable instructions for the management of fruits. We can forward it post-paid upon receipt of the price, \$2.00.

Quince Trees.—C. T. Bradley, Clearfield

Co., Penn. The unfavorable situation is probably the cause of the slow growth of your young trees. At the proper season they may be moved without risk. Suckers ought not to be allowed to grow, but the bushes should be trained with a single stem like an apple tree.

Cherries from Seed.—W. H. Coleman,

Ky. There is no probability that the seeds of any of our cultivated fruits will produce precisely like the parent trees; the stone fruits, usually vary less than others.

Osage Orange.—Several ask us about pro-

pagating this and its value as a hedge. The seeds cannot be obtained at present, and unless the plants can be found at the nurseries, its cultivation must stop until the close of the war. One subscriber wishes to know how to destroy an Osage Orange hedge. Doubtless, like other shrubs, it may be killed by cutting; when in full leaf, repeat the work as often as it springs up anew.

Propagation of Box.—Mrs. E. Cravath.

Box is most readily multiplied by layers. Set the plants out rather deep and spread the branches in such a manner that the lower portion of them will be covered with earth. Another season it will be found that the covered portions have taken root, and the branches may be pulled apart and set out as separate plants.

Propagating Flowering Shrubs.—

J. C. Dubois, Ingham Co., Mich. This may be done with many, by layering or removing suckers, according to the manner of growth. Some can only be grown from cuttings in the propagating house, where they will have bottom heat; but there are many cuttings, such as Roses, Weigelas, Forsythias, etc., which start very readily if kept from the hot sun. A hot-bed frame with the sash covered with whitewash, or cloth, or a frame of boards with cotton cloth tacked over one opening, will answer to shade them and keep them moist. Put the cuttings in rather sandy soil and keep them properly moist and shaded, giving them air when necessary.

The Death of Dr. Wm. Darlington.

This distinguished man died at Westchester, Pa., on the 22d of April at the ripe old age of 81. He was a representative of that class of old school gentlemen of whom we unfortunately have too few left, bringing the attainments of the profound scholar into an active life and participation with passing events. He was among our oldest botanists; about 40 years ago, he published the *Flora of Chester County*, which passed through several editions, each one keeping pace with the progress of the science, and it is still a standard work. Dr. Darlington was untiring in his efforts to arouse agriculturists to a sense of the dignity of their calling, and to inspire them with a love for the sciences connected with it. This is shown in his numerous addresses before Agricultural and Horticultural Societies, and in his *Agricultural Botany*, which, in its revised form, is now popularly known as *American Weeds and Useful Plants*. The interesting Pitcher Plant of California (*Darlingtonia Californica*), will keep his name fresh among scientific men, and his many useful labors will commemorate him in the community in which he lived. Though a Scholar, Patriot, and Statesman, he was at the same time, from his genial sympathy with those around him, a lovable old man.

Gray's Manual of Botany—(Fourth Edition).—Iverson, Phinney & Co., N. Y. When the first edition of this work appeared, it at once became the standard authority upon the flora of the Northern States, and it has through subsequent editions confirmed its title to that position. The works of Doct. Gray have the rare merit of being in a clear and popular style without departing from scientific accuracy. An intelligent person who carefully reads Gray's *First Lessons in Botany*, will have a clearer idea of the structure of plants than can be obtained from any other work in the language. The volume before us contains these *First Lessons*, a section on Garden Botany, and the *Manual proper*, which gives descriptions of the native and introduced plants growing North of Virginia, and East of the Mississippi, and includes the discoveries made since the last edition. An important addition has been made to the present edition of eight beautiful plates, illustrating the genera of Grasses. The study of these interesting plants, which is generally considered difficult, will be greatly facilitated by the help of these accurate delineations. The *Lessons and Manual* are sold separately, or bound in one volume, and will be found in our book list.

Prices of Books.—The cost of printing paper has remained nearly stationary for a month past, and the prices of books have not varied materially as will be noticed in the list on page 186. Until the paper market becomes settled, the publication of sundry books will cease as the editions previously on hand becomes exhausted, and prices of others will be advanced. There is no prospect of any decrease until long after the war is over, and it will be expedient to secure early, any book likely to be wanted. The prices in our list are good only for the month in which they are published. We do not keep a "book store," but usually have on hand or procure as needed, books relating to the Farm, Garden, and Household, for the convenience of our subscribers, and mail them *post-paid* at the usual retail price, though this affords but small profit—sometimes none at all.

Investing Money—Last Month of the Five-Twenties.—We referred last month (page 133) to the value, etc., of the U. S. Six per cent Bonds, called "five-twenties" because they are payable in 20 years, but the government reserves the right to pay them after 5 years. If this reservation were not made they would command a large premium. The same kind of Bonds not payable until 1881, are now selling at \$108, or 8 per cent. premium. The reason of this is, that foreigners and others, prefer a loan having a long time to run. A good farm mortgage of 20 years will sell for more than one of 5 years. We think these 5-20 Bonds are the best sure investment now in the market. It will be noticed that the privilege of taking these bonds at par expires with the present month. For further particulars, see last month's notice, and especially the full advertisement on p. 186, of the Government Agents, Messrs. Fisk & Hatch, who are careful, accommodating, and reliable Bankers. Those having funds in Savings Banks will do well to note the closing paragraph of their advertisement.

For the Hamburg Show—Free Freight.—The last steamer for Hamburg, by which articles can leave in time for the Great International Show, will sail from New-York, June 13th we believe. It may not be generally known that the Legislature of New-York appropriated \$1000 to be devoted to paying freight on articles manufactured in this State. This was placed under the direction of the State Agricultural Society, and the officers have decided to pay the expenses from the point

of shipment to Hamburg, including freight to New-York, and transference in the city. This places parties in all sections of the State upon a par. The articles are to be forwarded to the care of Austin Baldwin & Co., 72 Broadway, N. Y. Only the \$1000 can be so expended, which will be applied to the articles in their order of entry. For further particulars address Messrs. Austin Baldwin & Co.

Farm Help Wanted—and Coming.

A letter from Illinois says: "So many have gone and are going to the war from the patriotic West—we mean to open the Mississippi at least, if all have to go—that we can not get help to plant the extra acre you advise in the *American Agriculturist*, and if planted, we are not sure of help to cultivate it, or to gather the harvest. Can you not send us men from your over-crowded cities at the East? They can here get plenty of work at good wages, and abundant cheap food for themselves and families."

Reply.—The East is patriotic too, as the records of the War Department will show. For months past we have seen no men worth anything who have gone begging for work. Common laborers readily get \$1 to \$1.50 per day (without board,) which, deducting board and stormy days, is equivalent to \$13 to \$18 per month. We should hardly know where to look for a dozen men to send to the West. But the demand for farm help is in a fair way to be at least partially supplied, within the next two or three months. Never before has there been such an influx of able-bodied men from Europe—from Germany, and especially from Ireland. So great is the emigration from the latter country, that the British Government recently addressed a note to the American Minister, intimating that our Government must be using special influences to attract them away to our armies. Mr. Adams replied that no official influence had been used, but naively intimated that it was not surprising that so many were leaving oppression and want, and flying to a country where there is abundant cheap food and well-remunerated employment. We learn that this emigration is only limited by want of ship-room and the means of paying passage hither. The shipping facilities are being rapidly increased. We suggest that the German and Irish residents of this country be encouraged to send for their friends. They can still get here before the close of the harvest season, if they come by steamer. Let them understand that foreigners coming to this country will not be subject to the draft, unless they voluntarily take upon themselves the duties and privileges of citizenship; while their coming now will be a benefit to the country as well as to themselves. A man in Ireland, or elsewhere in Europe, with a dependant family, and with no prospect there but poverty and want, can by coming here earn enough the present year to send for his family, and place them where with cheaper and more abundant food he can not only support them, but lay aside something to build up for himself a home in the West ere long.

The Homestead Law allows any one who may hereafter become a citizen to choose a free farm from the public domain, where he can settle in a home of his own. There was never a more favorable time for the teeming population of the Old World to come to the New. Industrious men of good habits will be welcomed by farmers, at almost every point throughout the Northern States. Let these facts be properly set before the foreign population in our midst. A few dollars loaned to a servant girl, to be added to her savings, may often enable her to send for a father, or brother, or relative, whom she is now helping to support in poverty on the other side of the Atlantic. No doubt many farmers would find this a good way to secure additional help for harvest and Autumn work.

The Crop Prospects.—The result of the returns being gathered at the Agricultural Bureau, on the state of the growing crops, will not be ready before the publication of our next issue. From all we can glean from our correspondence and from exchanges, up to this date the general prospects of the crops are very good. There are some exceptions here and there, but these are confined to limited localities. The winter grain proved to be less injured by the open weather than we feared it would be. The late opening of Spring kept back the crops, and it retarded spring work so much that farmers are now greatly driven, but the May weather is hastening forward the growth of all crops in the ground. The fruit trees have bloomed very freely, and if no untimely frost occurs, the fruit crop will be very large. After two successive years of fine crops of almost all kinds we could hardly hope for a third one, yet that is the present promise. The result will depend upon the weather between now and harvest time. The only unfavorable thing for our country, is the apparently prosperous condition of the crops on the other side of the Atlantic. If this continue until harvest, it will largely diminish the foreign demand upon us, and perhaps depress the market prices here.

Are the Implements Ready?—A Scarcity of them Probable.

The present short supply and the high price of labor, may in part be remedied by securing more or better labor-saving implements. Two men with a mowing machine, horse-rake, and horse-pitchfork, will gather as much hay as eight or ten men using only the scythe, hand-rake, and common pitchfork. The same is true in regard to the reaping machine, the horse cultivator, etc. The more rapid gathering of a crop, at just the right time is a strong reason for using these implements. As we have often urged in the *American Agriculturist*, a man with a first-rate plow, hoe, ax, etc., will do nearly double the work in a week that can be performed by another man using poorer implements, while the extra cost of the former will often be less than the price of a single day's work.—Another suggestion. Those who intend to get new or improved implements this summer, should look out for them at once. Owing to the uncertainty in business matters, manufacturers generally did not provide their usual stock, while it is very probable that the demand will be greater than ever before. Indeed, the dealers in implements and seeds tell us that their business is already far exceeding any thing in past years. It will not do this year to put off the buying of a mowing or reaping machine, for example, until the week it is wanted, or there may not be one to be had at any price. Better have the orders in at once, that the manufacturer may prepare to fill them. Our advertising columns will indicate some of the present sources of supply. A note to the different dealers and manufacturers will obtain the terms etc., when not fully given in the advertisements. No time should be lost now.

About Advertisements—Explanation.

Numerous letters from subscribers seem to render an explanation necessary. The advertising pages, which are usually not supposed to be edited at all, are the most difficult labor assumed by the Editors of the *Agriculturist*. The reception of advertisements is allotted to one of them, who is instructed by the Publisher to exclude all unreliable men, or those believed to be so; all unknown parties who cannot give satisfactory references; all humbugs, secret remedies, patent medicines, etc.—in short, everything likely to deceive the readers. In these times, this is a hard rule to live up to. We are really giving back to our readers all their subscription money, and even a part of our advertising receipts, in the paper which we furnish them. It is also difficult for us to compete with other journals, almost all of which—not excepting the religious Press—admit to their advertising columns, things which the publishers would not have read aloud in their family circles. These semi-obscene advertisements, as well as those of humbugs, are of the most profitable kind; for those who make but a small return to their customers can best afford to advertise largely, and those who make their living out of the morbid curiosity of the youth of both sexes pay well for the privilege of bringing themselves to notice. We are sometimes offered \$2 or \$3 a line to insert such advertisements in the *Agriculturist*.—We still continue to follow the rule mentioned above, but would state, in answer to several letters, that we do not specifically endorse whatever appears in our advertising pages. Take, for instance, the manufactured manures, superphosphates, phosphatic guanos, etc. We do not buy or use many of these, and do not advise others to do so,—yet as many persons have a degree of confidence in these compounds, we allow responsible parties to advertise them. Again, with regard to new fruits, tree cotton, and recently-introduced plants generally, these may be desirable, or of doubtful utility, or even worthless. When we believe the parties are offering them for experiment in good faith, we admit the advertisements for the benefit of those who can afford to try them. Well-known public journals advertise with us, and these are of widely differing character. We of course do not endorse the politics or the specific religious views of any particular paper that uses our columns to make itself more widely known, if published by responsible parties. Excluding all whom we know to be dishonest or unreliable, we allow our advertisers to present their wares to the readers of the *Agriculturist*, presuming that they will exercise their own judgment upon them. Our advertising columns are well worth perusing; they keep the intelligent reader posted as to the recent improvements in agricultural implements, new plants, seeds, etc., and other matters of interest.

We strongly repeat our standing request that those who order or write to our advertisers, will let them know where their business cards were seen. It will please the advertisers, and be a material aid to our business department, as it is the success of this part of our paper that enables us to supply it at so low a rate.

The "Night Soil" of New-York City.

That night soil is one of the most concentrated and powerful fertilizers, has long been known; though from natural aversion, for wise reasons made instinctive, few persons are willing to turn this material to practical account. There are in this City, at all times, more than a million of resident and transient persons. If we estimate the night soil at only eight ounces per day for each inhabitant, the yearly amount would reach 182½ million pounds, or ninety-one thousand tons! This material would doubtless be worth to the fields of the Eastern States at least two cents per pound, if it were properly saved and mixed with the soil, or more than three and-a-half million dollars! Indeed we believe it would produce an increased product of crops worth five or ten fold this sum. Since the introduction of Croton Water, a large proportion of this night soil is washed into the sewers, and then out to mingle with the waters of the ocean. Still, according to the City Inspector's report, about 9,000 privies, vaults, etc., are annually cleaned by night scavengers, the contents being conveyed away in covered carts. The number of cart loads (25 bushels each) ranges from 40,000 to 50,000 a year. The extension of water pipes is constantly decreasing this amount. The carts are dumped into barges at a few points along the river. For the five years, 1861-5, the barges are furnished by the Lodi Poudrette Company, the City paying them about \$15,000 per annum. We recently visited the works of this Company, located on the west side of the Hackensack River, N. J., about half way between New-York and Newark, in order to see how they disposed of the material, and to learn from observation, whether it was honestly prepared for use by farmers. For twenty years past farmers have heard of the Lodi Poudrette, and large numbers have used it. Some of our acquaintances have purchased it regularly for from five to twenty years, and believe it a good investment. We made our visit to the works without previous notice, to the end that we might see just how the manufacture was carried on in the ordinary daily routine. The accompanying sketch gives a general view of the works. About six acres of swamp marsh, along the bank of the Hackensack river,

are occupied by the buildings and drying beds. This is, we believe, the most extensive establishment of the kind in the world, exceeding even the noted Poudrette Works near Paris. As will be seen in the engraving, there is a long wharf (about 1000 feet in length). Running parallel with this are a series of canals, or reservoirs, for holding the night soil as it is raised from the barges by means of buckets and poured into them. Sixteen of these barges (holding about 8000 bushels each) are constantly plying back and forth to the city, or lying at the wharves to receive the material. The end of one of the reservoirs is seen in the foreground. The emptying of the barges is done by a portable steam engine moved along the wharf to the different landing places. The material is dropped from the buckets upon a coarse screen which separates the larger rubbish—bricks, pails, boots, etc. In the reservoirs the dark green, semi-fluid mass partially dries down, the odors arising being from some cause much less offensive than we expected to find them. Back of these reservoirs are the drying beds where the men are seen at work with shovels. These are in part covered with board flooring, and in part are the smooth ground surface.

The manufacturing process is begun by spreading over the surface of the floors, a thin layer of muck dug near by, or alluvial soil brought from a point where it is washed out by the Hackensack and Passaic rivers. The night soil is then taken from the reservoirs, and a thick coating spread over the layer of muck. As it gradually dries out, the mass is shoveled over by large gangs of men, of whom 100 to 120 are employed at the works. This shoveling over and mixing is done several times, before the whole is dry enough to be taken in wheelbarrows to the screening buildings. In the latter it is thrown into large heaps, and again shoveled over to make the whole mass as uniform as possible. This is important, for if not done, the variable character of the night soil, as gathered from different parts of the city, might make one batch inferior to another.

The next process is to pulverize and screen the mass. To do this, it is shoveled into box sieves, and worked over and over, and beat with shovels until the finer portions fall through the screens. It is then ready for packing into

soil, during the different screenings, showing the privy vaults to be an "omnium gatherum" for all conceivable things, deposited in part by design, and in part by accident. We noticed brick bats by the scores of cartloads; bottle corks by the million; broken crockery of every possible kind, and some not broken; stove pipes; tin pans, tin pails, tin funnels, tin kettles, and about everything else made of tin; children's toys in inconceivable numbers, and of every kind ever made; beer bottles, stone jugs, glass bottles, and glass ware of all kinds; oyster cans, sardine cases, brooms, oil cans, carpets, old garments of all sorts; hats, boots, shoes, books, clock wheels, etc., etc.—not to mention bones, (some of them evidently human), many watches, gold rings, and other jewelry, precious stones, coins genuine and counterfeit in large numbers, counterfeit dies, etc. The workmen often find valuable prizes, which is perhaps one incentive to the following of a business at best unpleasant. Women gather the glassware and sort it, selling the different kinds at various prices, to be melted over, or ground up. They also gather the bones, the company paying a stipulated price per bushel. The establishment is worth visiting as a "curiosity shop" quite equal in some respects to Barnum's. Any one going there will need to provide himself with a good pair of boots, and, if having over sensitive nasal organs, to take along a bottle of hartshorn. Strange to say, however, the manufactured product, though containing but a small proportion of muck as an absorbent or dryer, is in the form of a dry powder, and nearly inodorous.

After being put in barrels, it is taken to the city warehouse, and delivered to the different steamboats, railroads, etc. Farmers take away large quantities in bulk. The fact that there are regular customers who come year after year, (we conversed with some of them who chanced to come while we were there), is fair evidence that the material is of practical value. It is used most largely for corn, a handful in the hill with the seed, to give it a vigorous start, a good development of the first roots whether on poor or good soil. Its great merit seems to be quick action upon young plants. It is not injurious to the seed, though in contact with it. Poor or heavy soil needs also coarser barnyard manure, to improve both the tilth and fertility.

barrels. These are all manufactured on the spot, the sawn staves being brought from Maine, the ready made heads from Massachusetts, and the hoops from various places. (The staves, heads, and hoops now cost about 18 cts. per barrel, and the men get six cents per barrel for putting them together, averaging 35 per day per man.)—We were greatly amused at seeing the immense masses of rubbish separated from the night

Management of Sheep in Minnesota.

To the Editor of the American Agriculturist.

As stern necessity is forcing an increased interest to be taken by Northern States, in the business of wool growing, I propose to give you a few practical items from Minnesota.

My neighbor Mr. Bennett, is the owner of about 2000 sheep, chiefly mixed blood, though a few are extraordinarily fine Spanish Merinos. He farms out about 1200, taking for his profits the fleece, and when the flock is returned, an equal number of young healthy sheep. The remaining 800 he feeds on his farm, and it is to the management of this home-flock that I would call attention, as I think that he has wintered them with unusual economy and success.

Mr. B. raised a quantity of Indian corn, which was cut and cured in the usual way in the field, where it was left standing in stack for daily use during the Winter. The feeding season with us is almost invariably free from rains. The corn was drawn and scattered over a large pasture at the rate of about one and-a-half bushels of grain to a flock of 200 sheep. The little animals stripped the stalks and cobs absolutely clean; then after being watered they were enclosed in yards adjoining the sheds, and supplied with an abundance of fresh straw, in racks.

Cost of Wintering.—Mr. B. estimates the cost as follows: In our neighborhood, unimproved land costs from five to ten dollars per acre. An acre of well cultivated and well cured corn, costing about \$5 for labor, will support 15 sheep, at 33½ cents per head. It is now the last of March, and he has still some weeks of provision left.

How the Sheep Look.—Under this head it is unnecessary to multiply words. The sheep are fully as fat as desirable. They are healthy, fleece heavy, clean, and in excellent condition. Mr. B. estimates his clip will average four lbs. to the sheep, including the last year's lambs.

How Sheltered.—Our climate, I repeat, is unusually dry during the Winter; we have few or no rains, or heavy snows, therefore but very ordinary protection is required; nor need we confine the animals to close, heated, and unhealthy stables. Sheds of rough boards, or poles and straw are infinitely preferable to the most costly and closely built stables. Mr. B.'s sheds open to the south, and are well boarded against north-east and west winds. They have a depth of about 16 feet, which gives ample protection, affording a dry, airy, healthful, and all-sufficient shelter. The pens and sheds are daily spread with clean fresh litter—the straw which the sheep pull from the racks. In warm days which come suddenly upon us as Spring approaches, the animals are driven to the open fields, away from the fumes of the heated manure, until the approach of night-fall, and in this daily care for the health of his flock, lies the true secret of Mr. B.'s success.

So soon as grass appears, pasturage with us is not an item of cost. A sufficient range is so easily procured, that at most it can only cost the wages of a man, who with a good dog, will look after and care for from one to two thousand.

The Profit.—According to present appearances Mr. Bennett's profit item will stand as follows: Sheep averaged when purchased.....\$2 20
2,000 Sheep at \$2.20.....\$4,400
Cost of keeping.....1,320—5,720

Sheep worth without the fleece, say \$5.....\$10,000
8,000 lbs. of wool, say 75c.....6,000
Lambs, say.....1,500

17,500
Deduct first cost.....5,720
Balance in Profit*.....\$11,780

You will observe that I have added a cost for Summer keeping equal to the Winter, which is

of course an excess; but I have made no allowance for loss by disease or death, which for six months past has only amounted to about \$10.

Having given you the above items I now solicit permission to propose a few inquiries to be answered by experienced sheep breeders.

1st. There is a prevailing opinion that the further north, wool and fur animals are grown within the limit of plentiful support, the finer and better is the growth of the animal's covering:—Is this only a conceit, or demonstrated fact?

2d. Do fine blooded sheep of the Eastern countries, degenerate in flesh or fleece by removal to the colder climates of the American States?

3d. Have sheep growers determined the quality of sheep natural to the temperate and colder climate of the Northern States of America?

The subject of wool growing is at this moment so pregnant with interest that it deserves much more than ordinary investigation. Thousands will be tempted to embark in the business, knowing little or nothing of the habits, the quality, or the wants of the animals. T. T. MANN.

Washington Co., Minn.

* Mr. Mann's estimate of profits is too large. His figures put wool at \$1 a pound, making the profits \$11,780: we took the liberty to change the estimate for wool in Minnesota to 75c., and that is nearly double the usual price. The present quotation in New-York (May 6) is 70 to 90 cents, from which must be deducted freight, commissions, etc. Again, is not \$5 a head for shorn sheep rather a high estimate for Minnesota. If one were to now embark in sheep growing, he would of course have to pay present rates for stock sheep, and not \$2.20, the price paid by Mr. Bennett. We readily grant that wool growing is largely profitable, and likely to continue so, but add these remarks as a caution against too great expectations.—Ed.

Shall Sheep be Washed?

Wool undoubtedly needs cleansing before it can be used in the manufactory, but it does not follow that it must be washed while on the sheep's back. There are many reasons why it should not be—few if any valid ones for a continuance of the practice. The best washing will only remove part of the foreign matter from the fleece. The manufacturer subjects all wool to a cleansing process, whether it has been previously carefully washed, or only "soused" in a slovenly manner. Sheep washing is violently unnatural. No animal dreads the water more, and with good reason; it requires days of warm weather to evaporate the moisture held in the meshes of a thick fleece of wool, and the animal not only suffers discomfort, but frequently positive injury. It is comparatively an easy process to remove the yolk and dirt from wool when sheared from the sheep, but impossible to complete the work while upon the back of the struggling animal. It would be just as wise, and little less humane, to give children an occasional plunge to remove stains and soils from their garments. But for the washing, the sheep might be sheared one or two weeks earlier in the season, which would promote heaviness of fleece, and add to the comfort and thrift of both sheep and lambs.

The great objection urged against shearing unwashed sheep, is that an unwarrantable deduction in the price of the wool is made by manufacturers. The remedy for this is with the producer. He has only to remain firm in a reasonable demand, and in time his terms must be acceded to. There is a very just cause of complaint in the practice pursued, of buying wool according to a general average of cleanliness, instead of fixing the price according to the actual condition of each lot. This has, in effect been, to offer a premium for neglect, and

many clips of professedly washed wool have been little superior in cleanliness to unwashed fleeces from sheep properly cared for. Producers should, in every case, insist upon selling their wool according to its own merits, and this can as easily be done with the unwashed article as any other. To change the present practice will require general simultaneous effort, and this can scarcely be expected without considerable discussion. It is here intended only to indicate some of the leading points that seem to make the change desirable.

Tim Bunker on Sheep Traps.

"What upon airth d'ye call that?" asked uncle Jotham Sparrowgrass, as he hailed Seth Twiggs in the street, this morning. Seth had a gun over his shoulder, and held in his hand what might have been mistaken for game, at a short distance. On closer examination, the object revealed a pair of short ears, a prominent nose, a long clean pair of jaws, well armed with sharp, bloody teeth. It was what is left of a dog after his tail has been cut off just behind his ears.

"That is what I call a sheep trap," said Seth, as he flung the head upon the grass, pulled his pipe out of one pocket, and a match out of the other, and lighted.

"Why that is Jake Frink's dog!" exclaimed Uncle Jotham.

"Taint Jake's any longer," replied Seth. "Ye see I caught him in the act, this morning airly. He was gnawing away at a sheep he had run down, and that is sheep's blood you see on his teeth now. I put that bullet between his eyes, and he hadn't time to clean his teeth before he emigrated to t'other country. That trap has caught three sheep of mine this Spring, besides lots of my neighbors, to say nothing of the lambs, and I was so afraid the trap might be set again that I jest cut his head off after I shot him, to make sure work of it. That critter has destroyed a hundred dollars' worth of property this Spring, I haven't a doubt. Sheep have been found dead, and badly maimed, and he has been seen chasing them. When complaint has been made to Jake, he could not believe he was guilty of even chasing sheep. He did not allow him in such tricks. His dog was as innocent as a lamb. Children could play with him, and he wouldn't even growl. To hear Jake talk, you would think the dog's mother must have been a sheep. Waal, now, ye see, that talk didn't go down with me. I can tell a sheep stealin' dog as soon as I lay my eye on him. There is a kind of guilty look about the critter, that says mutton, as plainly as if it stuck in his jaws. Jake has never been able to raise sheep. If he tried, his lambs disappeared mysteriously when that dog was a puppy. He always laid it to other folks' dogs. But Rover was the guilty wretch that drunk lamb's blood. I have been watching him for about a week, and ye see this morning I got him jest where I wanted him. There was a piece of mutton in his mouth when I fired. It will take a smarter man than Jake Frink to get away from that fact."

"I guess you'll catch it when Jake hears of it."

"He won't have to wait long, for I'm going to take home Jake's sheep trap this morning. I wouldn't have you think that I'd shoot a man's dog, and then not own it. That would be too much like a sheep stealing dog. I calculate to take the responsibility."

This conversation of my neighbors shows the way the current is setting in the dog question, and the progress the reform is making, under

the new laws, and especially under the high prices of wool and mutton. This last, I think, has more to do with dog killing, than all the laws that have been enacted. With wool at a dollar a pound or in that neighborhood, every body that owns land wants a few sheep. Even Jake Frink rubs his eyes and wakes up to the fact that sheep raising will be a paying business. Sheep will live and do well on his poor pastures where his cows grow poor. He will bluster of course, when he learns that his dog is killed, but he will be resigned and conclude that his sheep as well as his neighbors' will be safer with that sheep trap out of the way. A large number of poor farmers, and rather poor citizens, who have the dog mania will invest in sheep, and that will make them the natural enemies of dogs. I have noticed that it makes a mighty deal of difference whether it is your sheep or your neighbors' that are bitten or killed. Resignation is a virtue easily practised, when a pack of dogs get into your neighbor's flock and worry and slaughter. But when you go out some fine morning and find your fattest weather half eaten up, or your full blood Merinos made into mutton prematurely, it stirs the blood at once against dogs. You owe the whole race a grudge. You think of steel traps, bullets, and small stout cords in close proximity to dogs' necks. You talk fiercely and threaten vengeance. Men in such a humor are prepared to legislate rationally upon the dog question. They see very clearly that one vile cur, not worth a copper to any body, may easily destroy a hundred dollars' worth of their property in a single night. With sheep at two or three times the old prices we shall not only have good dog laws, but we shall have men that will execute the laws, and the dogs at the same time. The old arguments on this question are just as good as any new ones that can be brought forward, but men see them a great deal better. A sheep is a creature of consequence, just about three times bigger than it was two years ago. The dogs have grown small, and a multitude of them have grown out of sight entirely.

There used to be a dog on about every corner of the streets in Hookertown. Some families kept a half dozen, and they had tight match to get enough for their children to eat, too. Now they are getting scarce, and I am in hopes that the time is not distant when they will be confined to cages, and shown up as curiosities at Barnum's. It does my eyes good to see children and lambs fat and happy, and dogs lean and miserable. Fat dogs indicate a low civilization like the Chinese, or a low state of morals like the White Oaks, where the dogs are more numerous than the people.

I have hated dogs ever since I was a boy. My father kept sheep and was a lover of choice mutton, and chose to do his own butchering, in a humane and decent manner. I remember an old ewe with twin lambs, a cosset who came home with the cows to be petted, and cared for as if she were a member of the family. One morning she was found dreadfully torn by the dogs, just alive, but unable to move and her lambs missing. I have hated the sight of a dog ever since, and never pass one in the street, without an apprehension of a bite, and a great longing to brain him on the spot. Seth Twigg has given them the right name, "Sheep Traps."

And the morality of keeping a sheep-killing dog is on a par with that of a malicious neighbor, who should set steel traps in the sheep walks of your pasture. I would much rather have steel traps than the dogs. The trap would

be certain to dispose of only one sheep in a night, while the dog might kill or maim a dozen. The trap and the victim would be found together in the morning, and the mystery of the broken leg would be cleared up. But your cowardly sneaking dog does his work by night and is miles away in the morning, with his chops all licked, and lying by his master's door, as meek looking as if he never dreamed of mutton. The owner of a steel trap is a responsible being, but the owner of a dog seems to think that his brute is what Mr. Spooner would call a free moral agent, fit to do business on his own hook. He is not accountable for the deeds of his dog. I go in for trapping rats, skunks, foxes, weasels, and other vermin. If we must trap sheep and lambs, I prefer an article with steel springs and chain, to a pair of living jaws on four legs. The latter catches too much game.

Hookertown,
May 10th, 1863.

Yours to command,
TIMOTHY BUNKER ESQ.

Small Pox in Sheep.

It will be remembered that no little excitement was caused in England last year by the appearance of small pox among sheep. Active measures were soon instituted to meet the emergency, and we are happy to learn that they have been successful. An Association formed among the sheep breeders in Wiltshire, to prevent the spread of the malady and to afford compensation to those who might sustain loss by its attacks, has just closed its accounts, there being no present necessity for its continuance. The proceedings of the Association during the year are of general interest. When the disease first appeared it was recommended and practised to some extent, to inoculate exposed flocks, on the supposition that the malady would be less severe in its effects. This, however, proved not to be the case; inoculated flocks died off rapidly, and thus the proposed preventive only spread the infection. The Wiltshire Association instituted experiments to determine the efficacy of vaccine virus, which proved entirely satisfactory. Six healthy sheep were vaccinated and then confined with others that were diseased with small pox, and which subsequently died, but the vaccinated sheep resisted all contagion and remained perfectly sound. To put the experiment to the extreme test, the six sheep were afterward inoculated with small pox virus. Two of them died, two had the disease rather severely, the other two slightly, and the four fully recovered. The Association recommend instant isolation of an infected sheep, and the vaccination of those in the vicinity, as almost certain means of eradicating the disease.

The labors of the Association brought to light some startling facts concerning the introduction of diseases among stock by importations from infected districts. There remained no doubt that the small pox was thus brought in. According to Government reports, the cattle diseases of England rose in ten years from a yearly average of 14, to 5, 6, and 10 per cent. A Government commissioner stated that, in 1862 the loss from disease was at least three times the total amount of cattle imported, a large part of which was clearly traceable to the introduction of diseases from abroad. It is very justly considered a matter over which Government should exercise proper control, and it will not be amiss for American farmers to give the subject due attention in time. The Pleuro-pneumonia excitement, though somewhat exaggerated, shows how great the danger may be, and

as our flocks and herds become more valuable, and greater attention is given to raise the standard of excellence by bringing in new blood, the risk will be proportionately increased.

Cure of Foot Rot in Sheep.

To the Editor of the American Agriculturist:

I have repeatedly used the following treatment for foot-rot in sheep with complete success. Prepare a solution of blue vitrol as strong as it can be made, by pulverizing and dissolving in warm soft water. Each hoof should then be examined, thoroughly cleansed with a knife, and if too long, cut to the proper dimensions. If no infection be found, let two men take the sheep with a leg in each hand and dip every foot into the solution of vitrol. When an infected hoof is found, carefully pare it until every particle of the infection is exposed—avoid bleeding the foot if possible. Then thoroughly saturate the foot with spirits of turpentine from a vial with a quill inserted in the cork; pour on as much fine powder as you can make adhere to the foot or the parts infected, and apply a lighted match to the same; after which dip the foot in the solution as above directed. The sheep should then run on a clean floor until the remedies have had sufficient time to take effect.

I have cured an entire flock with a single course of the above treatment. But to be safe, the same should be repeated in five or seven days, and if any cases of infection be found, repeat again. Should an obstinate case be found where the rot has penetrated into the center of the quick, the sheep should be put into a pen or small yard by itself, and subjected every second day to the prescribed treatment. Thoroughness is the great secret of success in treating the foot-rot. The knife is the principal remedy, if sharp and skillfully handled. A SUBSCRIBER.

Middlebury, Vt.

Prevention of "Cribbing" in Horses.

To the Editor of the American Agriculturist:

I found myself cheated to the amount of \$50 by the purchase of a horse sold as "sound," but which proved to be an inveterate cribber. Various remedies were recommended and tried without success. Finally, I have found a preventive, if not a cure. I have arranged the stall so as to leave nothing against which he can press his teeth. He is fed from a low box which is pushed into the stall from a passage-way, and the box is withdrawn when not in use. (It is said that a horse can not crib with his head down.) The opening for air and light is placed too high for him to reach it, to crib against its sides. Since adopting the above arrangement, the horse has improved in condition and spirit, and his value is also much increased. X.

Salting Stock.

Probably we do not know all the uses of salt in the animal economy; but a few are obvious. It acts beneficially upon the liver, yields a supply of soda to the bile, and gives increased nutritive power to food. It acts as a vermifuge, keeping the bowels of stock free from worms, and gives increased tone to the stomach. It tends to prevent rot in sheep. As to the amount and the time of giving it, farmers disagree. Some are accustomed to salt their stock regularly, once a week. Many successful farmers keep salt within reach of their stock, believing that they will eat only as nature requires. *

Experience with Italian Bees.

To the Editor of the American Agriculturist.

July 3d, 1861, an Italian queen was received at my Apiary. During the last of that season, I reared six queens and introduced them into stocks that Winter. In the year 1862, under the same circumstances, the Italians did one-fourth better, and where I introduced them to some of my neighbors, they say that they have done one-half better than the common stock. Of two colonies that stood side by side—the Italian filled 14 4½lb. boxes; the common bees, filled 8 4½lb. boxes. In introducing Italian queens, I find that the common bees disappear in about 90 days. This season I intend to introduce a common queen to an Italian stock to test what is now theory, that is, whether the life of the Italian worker is longer than the common. Either this is the case, or the Italian queen is *very much* more prolific. That it is a more active worker I have no doubt; that it will defend its stores with marked promptness is also true. I have been troubled less with robbery from the Italian than the common bee. Last year until after swarming or dividing, I had over 100 colonies at my place; then I carried some to what I supposed were better honey producing localities. The Italian bee is larger when it builds its own comb. I notice that they fly earlier and later than common stocks of equal strength, also on a cool day when scarcely a common bee is out. If the Italian bee is abused, it will resent it more vigorously than the common bee, but with care they can be managed as well. This Spring my Italians are in good condition and I am much pleased with them.

Tipton County, Iowa. C. G. McNEIL.

[We print the above as one of the apparent results of experiments with the Italian bee; but it will require a great number of careful experiments, to finally decide whether or not the Italian bees, as a rule, are better workers, more vigorous, and otherwise superior to the common bees. In the above case, and in the few others reported, the apparent difference in the amount of the honey, *may* have resulted from other causes, as it often happens that of two common swarms, apparently of equal number and vigor, the one will store up double the amount of honey secured by the other, though no reason can be given for the difference. If the general experience continues to show a marked difference in favor of the Italian, there will then be good reasons for introducing them generally.—Ed.]

Sheds for Manure.

Some farmers would build sheds for their manure, if it were not for the trouble. Others would do so, if they did not fear fire-fanging, or waste by drying up. But the trouble is nothing to an industrious man, and if the heap is properly managed, there is no danger from excessive heat. By protecting it from wind, sun, rain, and *washing*, its value will be largely increased.

It is doubtless true that horse-manure alone, if covered, will suffer from too rapid decomposition. But this can easily be prevented by mixing with it, as the heap is forming, frequent "dividers" of muck, tan-bark or common soil. The very best way is to throw up rough sheds, without siding, over the port holes of the barn,

large enough to cover the dung-heaps and a large pile of muck. Every few days, after the stalls are cleaned out, let a man shovel an equal amount of muck over the pile of fresh manure. This will absorb the liquid parts and prevent "fire-fanging." And when this heap is finally shoveled over and mixed, the compost will be as valuable as an equal amount of simple manure.

We are continually hearing of farmers who *accidentally* learned the lesson we now teach. They now never think of leaving their manure "out in the cold." They know that the increased value of their manure annually is four-fold greater than the cost of their sheds.

Poultry—The Black Spanish Fowls.

This breed of poultry is deservedly becoming popular in this country. It has long been reared in Spain and the adjacent countries along the Mediterranean, where it is said to have been introduced from the West Indies. Bement, in his Poulterer's Companion says of it: "The thorough-bred Spanish fowls should be entirely black, as far as feathers are concerned, and when in high condition display a greenish metallic lustre; an erect brilliant scarlet comb, serrated; with a clear milk-white face and earlobes; dark-blue legs; and a lofty carriage. Wattles of the hen small, but large and very conspicuous in the cocks, and like the comb, of a light scarlet. This marked contrast of black, bright-red, and white, makes the head of the Spanish cock as handsome as that of any other variety; and in the genuine breed the whole form is equally good. The cock-bird should be strong and short in the legs as possible; his back from tail to neck short, tail large and ample. He should weigh not less than six pounds; the head is rather large, the spurs long and sharp, and the bearing and carriage proud and high. The face should commence from where the comb joins on the head, and must extend downward over and around the eye till it meets the white earlobes.

Spanish hens are also of good size and good figure, and are celebrated as good layers, producing very large white eggs. The head of the hen should be neat, and of moderate size; eyes bright; comb single, very large and pendulous;

face entirely white, the white extending around the eye; neck of moderate length, neatly set on; body broad, wings of middle size; legs a bluish-white; tail long and well squared; plumage of a glossy black, with brilliant tints of green and purple, as in the cock, but less brilliant. Her weight should not be less than five pounds. It must be especially observed that the slightest approach to coarseness, in either cock or hen, must be discountenanced, even at the expense of size; for in no class of fowls is fineness of quality more requisite and more appreciated than in the Spanish."

These fowls are favorites for their beauty, their excellent flavor of flesh, and their prolificness as layers. Such is their indisposition to sit, that it is advisable to depend upon hens of other breeds to rear their young. They are subject to one or two drawbacks. Their large combs are apt to be frosted during our northern winters, unless the birds are kept in warm quarters, and without proper care, mortification and death may ensue. They also are liable to lose their plumage, and if they moult late, they suffer from exposure.

Look After the Cabbages Early.

The importance of the cabbage as a field crop has hardly begun to be appreciated in this country, while in England, it ranks second only in value to the great root crops. As a food for fattening animals and as a change of diet for all, cabbages are highly esteemed. The crop is liable to the attacks of both insects and disease. The most common pest is the aphid or cabbage louse. If the plant is vigorous, it will soon outgrow its attacks. The sprinkling of ashes or air-slaked lime over the plants is recommended as a remedy. Mr. M. Scougal, of Mich., writes to the *Agriculturist*, that he has found it beneficial to sprinkle salt over the cabbages. Soon after the plants are set out, the cut-worm makes its appearance, taking off the leaves and sometimes the entire plant. The only remedy is to search for it just beneath the surface. It shows its tracks in the fragments of leaves, and the hole by which it has entered the soil. After the plants are out of the way of the cut-worm, they are preyed upon by the caterpillars of several species of butterflies. These, when young, are close together upon the outer leaves which may be broken off and the caterpillars destroyed. If over-looked until they get larger they become scattered, when hand picking must be resorted to. Cabbages are liable to a disease called club-foot, which shows itself in large swellings, or excrescences upon the root. This is by some supposed to be caused by insects, and by others regarded as a disease of the plant resulting from poor culture, and that the insects found accompanying it, are there because they find a favorable place for their operations, and are a result rather than the cause of disease. The only remedy that has been proposed for club-foot is to cultivate on land which has not been occupied by cabbages or any of the family for several years. In Massachusetts, where the culture is, perhaps, carried to as great perfection as anywhere else in the country, the best growers do not plant cabbages on the same land oftener than once in three or four years. In setting out the late crop this hint should be followed.

A Cart Weighing Machine.

Mr. J. S. Taylor, of Danbury, Conn., has left at the office of the *Agriculturist* a model of an apparatus which may be readily attached to a cart for the purpose of weighing the load. The engraving will give a general idea of the arrangement, though to exhibit it more distinctly, would require a separate engraving of the apparatus detached, for which we have not room. A long lever or scale beam, A, carrying a movable weight, B, is fixed upon a support or fulcrum, C. The whole is clamped by thumb screws to the axle of the cart in such a way that the weight comes upon the short arm of the lever, A. At D, is a compensating lever to hold the weight of the tongue. The supporting frame under the axle and the leg at D, are so arranged as to be turned up out of the way and allow the cart to be moved from place to place. When it is wished to weigh the load, these can be let down and the weighing performed. It is claimed that this apparatus will be found useful in weighing produce, etc., in those neighborhoods which have no large scales.

A Corn Coverer.

A "Prairie Farmer" sends to the *Agriculturist* a sketch and description of the implement illustrated below, designed for covering corn on smooth mellow land. This may be new to some readers; it has been for a number of years in use at the West, where it is called the "jumping shovel." The beam, B, is of 2x2½ inch stuff, 4 feet long. This is mortised into the post P. The latter is 2x2 inches, and 2 feet 9 inches long. The mortise to receive the tenon

of the beam is 1 foot from the lower end. The two are held together more strongly by a ½ iron brace under the beam. A 1 inch augur hole is bored 3 or 4 inches from the upper end of the post to receive a round brace which is fastened to and supports the upper end of the handles H. These are ¼ by 1 inch, in size, long enough for convenience, and bolted to the sides of the beam. The shovel S, is bolted to the lower part of the post. It can be made from

an old ditching spade, or a piece of steel 8x10 inches. It should have a straight edge at the bottom. To use the implement, the ground is first marked out both ways, two boys are employed to drop the seed, and a man follows with the coverer drawn by a horse. The shovel is kept in the furrow, gathering earth as it goes, and is raised a little at each hill, throwing the soil over the corn. The maker says that with a little practice a man can cover five acres in this manner as well and as quickly as one acre could be planted with a hoe.

Profitable Corn Raising in Connecticut.

In the Spring of 1862 the writer commenced preparing a newly purchased field of twenty-three acres, to be planted with corn. Most of the field was an old pasture lot, much grown to cedars and briars, stony, with a northeastern exposure; the remainder was mowing land, separated from the former by a deep ravine. We commenced operations by removing the division fences, clearing the cedars and stones, under-draining the wet portions, and plowing it all deep and well. Some parts that had never before been plowed, cost from \$6 to \$8 per acre. It was manured with 800 lbs. per acre of Quinipiac Co.'s Fish Guano, sown broadcast and harrowed in. Harrowed the field three times and brushed over once, marked the rows three feet nine inches apart each way, dropped in the hills a small handful of manure made by composting fish guano with soil, planted the corn with a hand corn planter, and covered with a hoe.

As soon as the corn was up, which stood very even, the ground was thoroughly stirred with a cultivator going each way, which was repeated three times during the season, and it was twice hoed by hand. The corn looked remarkably well, retained its dark green color, until very late, and ripened to perfection. An account of expenses was carefully kept each day, and the labor being all hired and paid for, prevented any difficulty in knowing the exact amount. Thus:

17 1-10 days plowing \$3 per day.....	\$ 51.30
7 days harrowing \$3 per day.....	21.00
1 day bushing \$3.....	3.00
10 7-20 tons fish guano \$33½ per ton.....	344.96
12½ days sowing \$1 per day.....	12.50
2½ days marking out \$2.50 per day.....	6.25
8½ days manuring in hill \$1 per day.....	8.25
3½ bushel seed corn \$1 per bushel.....	3.12
11½ days planting \$1 per day.....	11.50
Protection from birds.....	2.37
21 days cultivating.....	46.75
36 days hoeing.....	38.25
Interest on cost of land.....	50.00
Total expenses of crop.....	\$599.25
By 1000 bushel corn \$1 per bushel.....	\$1000
Net profit on the crop.....	\$400.75

The cost of harvesting is not taken into account, neither the value of corn-fodder, one is expected to balance the other. The yield was

determined by careful estimate, made when the crop was gathered, and by what has since been sold, and is considered below, rather than above the actual amount. The price given, has been received per bushel of 56 pounds. The wood paid the cost of clearing the brush off the land, and the increased value will more than balance the expense of draining. Let Western farmers beat it, if they can. HALL DICKERMANN.

New Haven Co., Conn.

[We'll agree to turn out any number of western farmers who will beat this, if Mr. D. will take the corn at half the price he names. The best corn has occasionally sold here the present year at \$1 per bushel, but 60 cents per bushel is as high as it will do to calculate upon. Many farmers upon the western prairies would get rich very soon, if they could depend upon 25 cents per bushel, one year with another. We do not make these remarks to discourage planting corn, nor to depreciate the experiments of Mr. D., but as a rule, eastern men, especially in New England, put too high a price upon their farm products, when reporting upon farm operations. Being nearer the market for consumption, they obtain much higher prices than western farmers, and can afford to work poorer land, and expend more in tillage and manure. Still, western men would find it pay better to go over less surface, or by better cultivation get the same amount of crops from smaller areas.—Ed.]

What Kills the Squash Vines?

Several correspondents have written to the *Agriculturist* that their vines were destroyed last year to such an extent as to discourage them from attempting to raise squashes. One succeeded in ripening only a single Hubbard Squash from a packet of seeds sent from this office. The vines, apparently in full vigor, suddenly die, and when cut open, are found to have a worm or borer near the root. The destructive worm is the larva of a rather pretty insect, called *Trochilium cucurbitae*, or Squash-vine Borer. We give an engraving of the perfect insect from

a drawing kindly furnished us by Prof. Glover, the entomologist of the Department of Agriculture at Washington. The forewings are black and the second pair transparent; the body orange colored, and the hind legs furnished with long fringes. The insect deposits its eggs, which are very minute, from June to August on the stem of the vine near the root. The larva penetrates to the interior of the stem, and by eating away the substance kills the plant; after it reaches its full size, it enters the earth and forms a cocoon of a gummy substance covered with particles of earth, from which the perfect insect issues the following summer. These are the habits of the insect, and as will be seen, it is a difficult one to exterminate, as its presence is not suspected until the mischief is done. If the moths are seen flitting about the vines, every effort should be made to entrap them. The vines should be examined daily, and if any one is observed to droop, the larva should be searched for in the stem near the roots and cut out as carefully as possible, hilling earth around the stem, so as to cover the wound. If a vine is killed, care should be taken to destroy the insect which has done the mischief, to prevent multiplication.

For the American Agriculturist.

A Finality on Rats.

No pests are more annoying to the farmer and housekeeper. The destruction of property by them in the aggregate, is enormous. Many a farmer loses more by rats than the whole amount of his taxes. They burrow under the pig-trough, and come as regularly for their feed, as the pigs themselves. They share the food of the poultry and the horses and cows, if they are grain fed. They show themselves in the barn and house cellar, and devour the roots stored for Winter use. Thus there is a continual waste, and the amount in the course of the year is very large. But this is not the worst part of it. The scoundrels are so cunning that they outwit us, and evade every effort to oust them. Set traps for them, and you rarely catch more than one in a place. Stop up their holes, and they dig new ones. Set poison for them, and after a single night's experience the survivors will not touch it. A few are killed but all their neighbors come to the funeral and occupy their places. Put your cat in the barn, and they only withdraw to the house cellar. Put her in the cellar, and they flee to the barn. Occupy both with cats, and they flee to the corn crib. Wherever there is a chance for depredation, there the rats do congregate and multiply with astonishing rapidity.

What can be done? There is no effectual remedy but to make your buildings rat proof. The corn crib is easily insulated from rats and mice, by setting it on four posts capped with inverted tin pans, or large flat stones. The posts should be three feet high and the steps to the door should be movable, and should be taken away whenever the door is shut. But other buildings with cellars must be cemented on the bottom, and have the walls pointed with mortar in order to exclude them. This work fortunately is easily and cheaply done, and no man need go without a cemented cellar bottom for lack of skilled labor to do the job. He can do it himself. The articles wanted for the mortar, are sand and common water lime, which sells ordinarily in the New-York market from \$1½ to \$1¾ a barrel. Builders and masons in our large towns and villages, generally keep it on hand. The sand should be as pure a siliceous as you can find, and if the grit is coarse, so much the better.

To make the mortar, take two parts sand to one of cement, and mix thoroughly in the dry state, then apply just water enough to have it work well, and lay upon the cellar bottom with a trowel an inch thick or more. Only so much should be mixed, as you can use immediately.

If you do not wish to employ the mason, you can make your work rat proof without him. First prepare your cellar bottom by making it level, and ramming it so that it shall be as hard as a foot path, then apply the mortar and smooth it with a trowel. The thickness of the cellar bottom will depend upon the use you design to make of it. If you wish to drive a cart over it, as is necessary sometimes in large barn cellars, it should be at least four inches in thickness. In this case it is well to mix with the cement, gravel of the size of hens' eggs or smaller. If it is a cellar bottom, simply to hold manure, or to store roots in, an inch in thickness is just as good as more. In this case you should dig a trench say four inches deep by three broad, immediately adjoining the cellar wall on all sides and fill it with the mortar. The point of danger is immediately by the wall where the rats seek to enter. This also may be mixed with sifted

gravel stones. When their teeth bring up against the gravel, it rather blunts the edge of their voracity. The expense of cementing the cellar of a common sized house, say thirty by forty feet, will not be over ten or fifteen dollars, not counting the labor. Many a farmer loses more than this in a single season. The cementing is a work done for life and we have found it to be very effectual. CONNECTICUT.

["Connecticut's" suggestions are good, irrespective of cemented bottom cellars being proof against rats. Unless, however, the walls and the earth outside are made solid with the cement, the rats will do more or less mischief outside the walls.—In the April *Agriculturist*, page 119, we referred to using a "phosphorus salve," bought in Fulton-st., (we forget the name and number,) and are glad to report that the rats and mice are still absent. Not a dead one has been seen, or "smelled," and we conclude they went elsewhere. The remedy proves so effectual, even in our buildings which contain so many inviting seeds, that we shall advise Mr. Lane, of the Purchasing Agency, to hunt up the material, and advertise it in this number.—ED.]

Talks About Weeds.

Perhaps few persons have taken into account the immense labor, expense, and care involved in the destruction of weeds. A large proportion of all the work required in the cultivation of the hoed crops, arises from the necessity of keeping these pests in proper subjection. If weeds did not grow, we could dispense with half of all the labor now expended in growing our thousand million bushels of Indian corn; and so of the turnip, the onion, the tobacco, the cabbage, etc., and of nearly all garden products. This subject is so important, that we deem it worth while to devote a few chapters in the *American Agriculturist* to the discussion of the habits of the principal weeds, with hints upon the best modes of exterminating them. And first, a few general considerations.

We have many letters inquiring how this or that particular weed may be killed; the mistaken idea being that there are specific poisons for the destruction of the different noxious plants. A weed is any plant which grows where it is not wanted, no matter whether it is in itself beautiful, or useful, or not. Rye, a useful plant when grown by itself, is, when mixed with wheat a troublesome weed; and many of our choicest garden plants are weeds in other countries, while some of our common weeds are cultivated elsewhere for their beauty. Weeds are subject to the same laws of growth, and flourish or languish under the same conditions as other plants; any destructive agent or poison that would kill them, would destroy the useful plants also. In cultivation, to serve our own purposes, we place certain plants in an unnatural condition—a condition which alone makes them valuable to us. We all know how perfectly worthless the common carrot, parsnip and turnip become if allowed to run wild, and doubtless without the care of man, a majority of our cultivated plants would become equally valueless. A given space of soil can sustain only a limited number of plants; those of a naturally strong growth, or which find the locality favorable to them, live and flourish, while the weaker ones or those unsuited to the locality, are killed out by the greater vigor of the others. This is the natural state of things. Cultivation gives a plant the best possible chance to develop itself, and

to do this we not only supply an abundance of the kind of food best suited to its growth, but also remove all other plants which would interfere with it, and thus give it full possession of the soil, and relieve it from the necessity of struggling with competitors. In preparing and enriching the soil for the desired plants, we at the same time adapt it equally well for those not desirable. If a field is planted and left to itself, all have an equal chance, and the probability is, that the undesirable plants, or weeds, will either obstruct the growth of the cultivated plant or kill it out altogether. In cultivation we must not only give our plants the best chances as to food, but must also see that they have full possession of the soil prepared for them. The practical part resolves itself into two questions: how do weeds get into the soil; and, being in, how are they to be exterminated. We must recollect that nature makes abundant provision both for the reproduction and the preservation of every plant, no matter how insignificant, or troublesome even, it may be, and we can not work for the growth or the destruction of any plant unless we understand its peculiarities and treat it accordingly. Take any field which we wish to cultivate, and plow it up; if left untilled, it will be found that there were already seeds enough in the soil to completely cover it with vegetation. If we manure the field, a host of seeds will be introduced in the manure. Not only this: numbers of plants of the thistle family have their seeds furnished with down, and every breeze will bring hundreds of them from the neglected field of some careless neighbor; cattle and sheep may bring them in their hair and wool; even the workmen will bring them attached to their clothing, and birds will deposit them in their excrements. If the field is where it is overflowed by freshets or where it receives the wash of other lands, multitudes of seeds will be brought in by water. It will be seen that there is abundant provision for seeding the soil to weeds. As already hinted, the vegetation which first gets possession of the soil, tends to keep other plants out, hence it will be seen that the early destruction of weeds tends to give the crop the advantage; this of itself, is a great point gained.

Weeds have three general modes of growth: 1st. The annual weeds, or those which start from the seed and perfect themselves the first year, like purslane and shepherd's sprouts: 2nd. The biennial weeds, which pass the first year in making strong roots that bloom the second year and die, as the wild parsnip and carrot: 3d. The perennials that may or may not flower the first year, but which keep on growing and make a strong mass of underground roots and stems that soon get possession of the soil to the exclusion of all other vegetation, as the Canada thistle, and the dock's. The free use of the hand hoe and the cultivator, will destroy the annuals, and also the others while they are in the early stage of their growth. It is only when the last two sorts get possession of the soil that there is any serious trouble. When they are old enough to have made large roots or tubers they then have a store of material from which they can throw up numerous shoots; and this they do so frequently and so rapidly as to give the impression that it is impossible to kill them. Any of these plants will die, if not allowed to produce leaves. Frequent mowing or, if not too numerous, cutting just below the surface of the ground will ultimately exterminate them. The underground supply of food which these plants have stored up, must give out, if it be not replenished by the growth of leaves. If the cultivator

only persevere, the conquest is certain. Weeds of whichever class, should not be allowed to perfect their seed. A single weed that goes to seed, provides for incalculable labor in the future. (See interesting figures in the next article.) With these considerations we leave the subject to take up some of the weeds in detail, at another time.

Multiplication of Weeds—Interesting and Instructive Figures.

Did the reader ever make an estimate of the rapidity with which plants multiply, especially those classed as weeds? A few years ago, while detained several hours at a railroad crossing in Pennsylvania, by the failure of a train, we went into a neighboring cornfield, and pulled a single stalk of the Ragweed (*Ambrosia artemisiifolia*) so common in some parts of that State, and sought amusement and instruction in counting the number of seeds. Sorting the average sized spikes, and counting the seeds on several of each, we found the number of perfect seeds grown that year on a single plant to exceed 16,000! Suppose each of these seeds to be scattered and grow, and go on multiplying: in the short space of only four years the number of plants growing would be 65,536,000,000,000,000, or about a dozen plants for every square foot of the entire earth's surface—land and water included. But suppose we take the average annual multiplication at only 100, which is far below the average increase of most weed plants. At a hundred a year, a single seed would in the tenth year produce 1,000,000,000,000,000 plants! This is equivalent to 111 plants for every square inch of the entire earth's surface; or 444 plants to every square inch of land, if we take the usual estimate that three-fourths of the surface is covered with water. Let the readers of the *American Agriculturist* apply these figures to their own farms or gardens, and estimate how long it would take a single weed seed to produce plants or even seeds enough to carpet the whole surface. They may then appreciate the importance of not allowing a single noxious plant of any kind to perfect its seed.

Arithmetical Note.—If we estimate the earth to be a perfectly round globe 8000 miles in diameter the following figures give contents and surface:

Solid Contents in Cubic miles.....	268,083,200,000
Surface or Area.. Square miles.....	201,062,400
Surface or Area.. Square feet.....	5,605,298,012,160,000
Surface or Area.. Square inches.....	807,162,913,751,940,000

Transplanting—Why, and How.

This is the month in which many of the plants in the kitchen and flower garden will be transplanted; that is, removed from the place in which they were sown to that in which they are to perfect themselves. As nothing of this kind happens to plants in their wild state, it may be asked if this is not an unnatural operation. To this it may be replied, that all cultivation is in a measure unnatural; it consists in giving the plant those advantages which it can only enjoy under the care of man. We take advantage of certain capabilities and tendencies of plants, and direct them to serve our own purposes. When we dam a natural stream and make an artificial pond, we alter the course of nature, but in order to do it successfully, we must work in strict accordance with natural laws. So in cultivation, we induce a plant to grow differently from what it would if wild, but in doing this we follow the laws which govern its growth in the natural

state. We do not oppose, we only direct. The leaves and roots of a plant bear direct relation to one another; if from any natural or artificial cause the root-growth is cramped or checked, the leaf-growth is correspondingly diminished, and the plant shows a greater tendency to produce flowers and fruit. Tomatoes in pots will show blossoms when only a few inches high, while if sown in the open ground they will make quite large plants before they show any signs of flowering. Now transplanting, no matter how carefully it may be done, by breaking off the minute root fibers has a tendency to hasten the maturity of the plant. It does this in a less striking manner it is true, than when the plant is grown in a pot, but it greatly modifies its development, and flower and fruit are borne much earlier. This tendency to early maturity is sometimes increased by two removals; the plants are taken from the seed bed and "pricked out," as it is called, into another bed, from which they are finally removed to the place where they are to mature. Each removal breaks off and shortens some of the branches of the root and, after the first shock is over, new small fibers or feeders are thrown out which, from their increased number, enable the plant to grow with much greater vigor than before, and mature much earlier than it would have done if left to grow where the seeds were sown. Sometimes there is an advantage in clipping the long or tap root in order to induce the formation of fibrous roots. As the functions of the roots are disturbed in transplanting, it follows that the relations between their absorbing surface and the evaporating surface of the leaves are broken up; the plant gives off moisture by the leaves more rapidly than it is received by the root, and the plant wilts. This indicates that a moist atmosphere is the most suitable time for the operation,—a "drizzly spell," when the soil is not too wet. It frequently happens that the plants are getting too large and there is no prospect of a damp season. Transplanting can be done, with proper precautions, at any time. For several years past we have been accustomed to work without regard to the weather and have been uniformly successful. If the holes are well watered and the plants are shaded for a day or two, they rarely fail to do well. The shading is easily done with a handful of cut grass, a burdock or other broad leaf, or a shingle stuck in a position to ward off the sun during the hottest part of the day. Where the plants are few and stand thinly in the seed bed, each may be carefully lifted by the trowel so as to retain a ball of earth around the roots, and removed with comparatively little disturbance; but where there is a large garden this particular care can not be exercised—all the operations must be carried on in a wholesale way. Where many plants are to be removed, they should be carefully lifted from the seed bed, separated and "grouted." Grouting consists in coating the roots with thin mud, which protects the delicate fibres from drying, and should always be done where the plants are to remain for some time out of the ground. The directions for grouting plants can not be better given than by quoting from Watson's *American Home Garden*, which by the way is one of the most reliable and practical works ever published in this country. (Price \$1.00.) "Grouting is performed by mixing rich earth, to which cow dung may be added, with water, to the consistence of soft mud, and dabbling the roots of the plants in it, not by thrusting them through it, but rather by drawing them through it, or, as it were, striking them upon it until each root is loaded. A dozen plants may be

grouted at once; and as they are held in the hand preparatory to this process, an inch or two of the root end may be cut off." In transplanting in the large way, labor can be profitably divided: one hand can make the holes with a trowel, another can drop the plants, and one or two may follow to set them. The plant should be set somewhat deeper than it originally stood, and the earth should be well pressed around the roots. If the transplanting is done in dry weather, the holes should be filled with water; when this has soaked away the plant should be put in and its roots covered with moist soil taken from beneath the dry surface. We always add a little dryish soil over the surface, especially if the earth used in filling be damp; the dry soil absorbs the surplus water, and keeps the mass from baking. We prefer making rather large holes with the trowel, to the use of the dibble, which in making the holes for the plant, packs the earth too closely for the favorable growth of its roots. The proper time for transplanting the different varieties is mentioned in the Calendar of Operations for each month.

How to Save Paper.

Those correspondents who write us long articles upon the way in which wheat may be converted into chess, and on the influence of the moon upon vegetation should, in these times of the high price of the article, save their paper. We can not publish such communications. Our position upon the chess question has long ago been defined, and although we have had much talk about the conversion of wheat into chess, we have had no proof that it has ever taken place. Let us have the specimens and we will submit them to the best authorities in the country, and if they decide that a specimen has grown part wheat and part chess, or is in an intermediate state between the two, we will give it up. Proof that chess grows where wheat grew before is no better evidence that wheat turned to chess, than finding a cow in a horse's stable is that the animals have been transmuted. Gentlemen troubled with chess upon the brain, please excuse us until you have some facts. Regarding the moon question, we are only sorry that this superstition exists among otherwise intelligent people. The weeds of error are some of them very tenacious of life. Melons and cucumbers are said to be particularly influenced by the moon. The *Agriculturist* advises to prepare the soil well, keep off insects, and put on liquid manure, and let the moon do her worst.

Fill the Missing Hills.

A vacant hill will be found here and there in the cornfield, at the first hoeing. Unless many of them occur together, they are quite likely to be passed by as of little account, but it is attention to small matters that marks the difference between carefulness and neglect, and not unfrequently here is the turning point between thrift and what is called bad luck. In most sections it will pay to replant missing hills with corn at the first weeding. In a favorable season it will come to maturity. Or pumpkin seed may be put in, which will yield choice morsels for animals next Autumn. It would be better to plant and cultivate these spots even without return, than to leave them to be occupied by weeds which will be sure to take possession, and ripen seed for a succession of troublesome crops.

GOING TO THE HAY FIELD.

Engraved for the American Agriculturist.

The above engraving, from an English painting, shows the bright side of Haying time in that country. The artist represents the whole family going forth to participate in the labors which are to transform the waving grass into stores of winter forage. The girls as well as the boys, will have a hand in the business, and their ruddy cheeks, when they return at night, will glow with the bloom which healthful exercise imparts. Even the baby is taken along to nestle and crow in a bed of new mown hay. Last season we saw many English haying scenes, none exactly like the above, but there were often gangs of thirty to fifty men and women all in one field, and when done there, they passed on to the next estate. The almost perpetual rains there, required much more "making" of the hay than in our dryer climate. We felt half tempted to set up the business of supplying "hay-caps," for we are quite sure they would be a god-send there. They pay with us, where much longer seasons of dry weather can be depended upon.

Were we presenting an American scene, we should perhaps show only two persons, one driving a mowing machine, and the other following with a horse-rake. Our labor-saving machines have in many sections of the country done away with much of the picturesque and poetical in hay-making; but we can afford to loose these if they bring us larger crops and in enlarging our home comforts help us to a higher civilization. Still, on many farms, especially in new countries, the scythe, the hand-rake, and the pitchfork are to be used in securing the great hay-crop,—great, for it is more valuable than cotton was in the best days of its reign,—great, for it is part of an ever present miracle, an intermediate stage between gross earthy material and life sustaining milk and meat.

It is not in Europe alone that women go into the field. In this war time, where the absence of men has made labor scarce, women, who are ever in advance of men in patriotism, take a share of the farm labor upon them. We have

just now a letter from "Elizabeth," in Iowa, who says: "Last year I helped my father stack our hay, nearly twenty tons, and felt all the better for it. I am willing to work out of doors for years yet, and let my brother fight for our country. I would rather do it than that one star should fall from our glorious old Flag."—With such women as these to take care of the homes, who shall despair of the country!

HORSE PITCH-FORKS.—Next to the mowing machine and horse-rake, the horse pitch-fork will be found the most valuable labor-saving implement for the hay making season. Very good forks, with pulleys and ropes complete, cost about a dozen dollars, the interest of which is less than a dollar a year. With one of these, a load of hay is quickly and easily raised and deposited in the highest mow, by a horse. Several kinds are made, any one of which is better than none. Two good ones were advertised last month, and they may be in this paper.

Cultivation of Beans.

The small crop last year together with the great demand for the army and navy, have caused beans to bear so high a price that doubtless many farmers will be induced to give more attention to this crop than formerly. The common bean has run into a great number of varieties, but the white sorts only are raised for use in the dry state, though some colored ones are much richer. The principal varieties grown in the large way are the Blue Pod, Marrow, and Pea-Bean. The earliest of these is the Blue Pod, which is a favorite sort in New England, on account of its early maturity and prolific bearing. The Marrow, called also White Marrowfat, is a favorite sort, and by many preferred to any other for cooking. The Pea-bean, also known as the army or ship bean, is quite small and rounded, and is the kind more largely cultivated. The soil should be warm and light, and not too highly manured; almost any but a heavy clay soil will answer. The planting is best done as soon as danger from frost is over, but if put in any time before the last week in June, they are pretty sure to make a crop. They should be planted in rows about 2½ feet apart, or sufficiently wide to allow of working with the cultivator. They may be planted with the hoe, putting 3 or 4 beans in the hill at a foot or fifteen inches apart. There are bean drills which do the work expeditiously, some of which drop the seed in a continuous line, and others are so contrived as to plant in hills. From a bushel to six pecks are used for an acre. Though the planting is generally left until the press of Spring work is over, it is advisable to get them in as early as possible, both on account of having them out of the way of early frosts, and to have the land clear for Fall crops. Do not let the weeds get the start, but hoe as soon as they make their appearance. Ground that has been cultivated with beans, is in excellent condition for wheat.

Try a few Roots.

Were animals competent to advise as to what should be grown and stored for their winter sustenance, there would be a unanimous request for at least a few carrots, turnips, or beets, to be fed with the dry hay which must form the staple diet. This request should be freely granted—not merely in kindness to dumb creatures, though that is something. It makes a man feel pleasant to witness the welcome which attends the distribution of an occasional juicy breakfast to stock that have been longing for something succulent. Variety of food promotes appetite and growth as well as pleasure to the animal palate. It is also no small help to the hay mow and grain room to have a well filled bin of roots to draw from. Although a given weight of grain will add more pounds of flesh than the same amount of roots, yet a larger quantity of food per acre can be secured from the latter. Fifty bushels of corn is above the average yield; with fair cultivation twelve hundred bushels of mangel wurzels can be produced, and much more by proper manuring and tillage. But there is less need than formerly to urge the cultivation of root crops, particularly in the older settled portions of the country. At the far West where corn and hay are almost superabundant, these may suffice; but throughout the East the benefit of root culture is yearly being more highly appreciated.

There is yet time to put in a winter supply

of ruta bagas, beets and carrots. White turnips are better left until July. Sugar beets and mangel wurzels should be planted early the present month. Carrots head the list for all kinds of stock, including horses; next we prefer beets; the mangel wurzel is most productive. All roots need rich, deep mellow soil. It is discouraging to an enterprising beet or carrot to plow its own way into a hard subsoil. Straggling roots here and there may find a small crevice in which to burrow, but the crop under such circumstances will be stunted and poor. A well tilled field occupied by corn the previous year will usually be a favorable location; a good dressing of old manure should be well worked into the soil. Much labor will be saved if the land be free from weeds. The first crop of these may be mostly destroyed by plowing early, allowing them to spring up, and then going over the whole with a cultivator harrow. The seed should be put in drills two feet apart for mangel wurzels, or ruta bagas, and sixteen or eighteen inches for carrots: nothing is gained by crowding the ground. At the first hoeing, thin the beets to one foot apart, the carrots to six inches. About four pounds of beet seed or two pounds of carrot seed per acre will be required. The after culture will consist in keeping the ground clean and loose. Almost the whole of it can be performed with the horse-hoe. It may not be advisable to commence largely at first, but we feel assured that those who commence with a quarter of an acre by way of experiment this year, will increase the size of the plot in future, particularly if proper attention be given to the first investment.

Interesting to Flax Growers.

It will be remembered that we published in the May No. of the *Agriculturist*, page 140, the decision of the committee of the N. Y. State Agricultural Society appointed to examine the various processes for the improved manipulation of flax, with a view to award the appropriation offered by the Legislature. It having been deemed advisable to retain the appropriation for another year, the Executive Committee desire to procure all possible information concerning the progress of flax culture and manufacture in this State. To this end they ask for communications from those interested, on the following points, viz.: 1st, The breadth of land sown with flax in the year 1863 in each town in the State. 2d, The amount of seed sown per acre. 3d, The amount of seed and straw raised per acre. 4th, The price received per ton for the straw, and for seed per bushel. 5th, Such other information relative to the culture of flax as the cultivator may deem essential. 6th, The amount of straw purchased by each factory, and the price paid for it. 7th, The purpose for which it was manufactured, as, for instance, paper stock, upholsterers' purposes, or flax cotton. 8th, The invention of any new machines for dressing flax. Letters containing information on the above points should be addressed to "Flax Committee, State Agricultural Rooms, Albany, N. Y." Such information will greatly facilitate the investigations of the committee into the important interest committed to their care, and will undoubtedly be cheerfully imparted by those of our readers in this State who are engaged the present year in flax culture, even though they may have just commenced on a small scale. The difficulties and observations of beginners are frequently of great value. Those just commencing often note points

which are passed over as unimportant by the more experienced cultivator, but which are of great weight in determining the essentials to, and probabilities of success.

A New Humbug.

Most of the Humbugs by which operators seek to fill their pockets at the expense of the credulous, are old games, which have been so frequently exposed, especially in the columns of the *Agriculturist*, that only those who will not read are in danger of being taken in by them. Only occasionally a new scheme is brought to light. Here is one having the merit of some originality. A highly patriotic and philanthropic individual issues circulars announcing that

* * * *

"The proprietor of one of the most valuable and successful, as well as popular and indispensable 'FAMILY REMEDIES' known in this country, has resolved to dispose of and close up his extensive business, for the special benefit of our SICK AND WOUNDED SOLDIERS, and the Widows and Orphans of those who have sacrificed their lives, and those who may hereafter, for the Preservation of our Glorious Union! The entire net proceeds shall be given to the above named persons, throughout all the Loyal States, and the amounts to correspond as nearly as possible to the number of troops drawn from each; for which purpose he hereby offers and agrees to give the RECIPE with the right to make and use the same, to every Family in the United States, for the small sum of ONE DOLLAR for each family."

EXTRA INDUCEMENTS are offered: Immediately upon the close of the Enterprize a grand Octavo Volume is to be published, containing the names of the Donors in regular order. Those who give five dollars, shall have their names printed in capitals; those giving ten dollars are to appear in capitals, and have a copy of the volume splendidly bound; and those who are thus patriotic to the amount of a hundred dollars, are also to have their Portraits superbly engraved in steel for the volume, and receive twenty-five proof copies extra? He who gives the largest amount is to have his portrait, lots of books and proofs, and his biography printed in the volume. A numerous signed certificate sets forth that the Manager is a gentleman of unblemished character, possessing superior business capacities of the strictest integrity. This man's "business capacities" may be of "the strictest integrity," but we can hardly vouch for his personal honor. Happening to know one of the parties whose name was appended, we inquired into the particulars, and were informed that the certificates were signed in reference to another entirely different enterprize, apparently a legitimate one, and that the signer considered the present scheme a transparent humbug. How many will be induced to swallow pills, or apply a lotion, for the benefit of the poor soldiers? Probably not many readers of the *Agriculturist*. Those who are disposed to help the afflicted in their country's cause—and who are not?—will find abundant opportunities to do so without sending a dollar to an unknown adventurer, who appeals to the unworthy motive of vanity, by promising to exhibit their names in print with others who may have been similarly duped, and in case they have been largely "sold," to show their portraits to an admiring world.

A THISTLE PULLER.—Julius Meyer, Potter Co., Pa., eradicates thistles by pulling them out by the roots before blossoming. To save the

hands, he uses a pair of wooden nippers of 2 inch stuff, 3 feet long, with teeth fitting into each other. This will exterminate them if properly followed up. Where they are very numerous it would be a tedious undertaking.

Precautions Against the Weather.

Science has not yet enabled man either to certainly predict or to change the weather. Although in general, the succession of the seasons, seed time and harvest, are guaranteed by the Almighty Ruler, yet they are not alike propitious to all localities. At times the North is blasted with untimely frosts, while the South is fervid with sunshine; the East may be parched with drouth, while the West is rejoicing in refreshing showers. But the cultivator may do something to provide himself against such contingencies. First, by a mixed husbandry. If corn be stunted by continued rain, the grass in meadow and pasture will grow with unwonted luxuriance, and what is lost in the plowed field may be found in the cattle yard and the hay mow. He who depends upon wheat alone may grow rich if the snows of Winter and the rains of Summer are propitious, but he may also lose all when the seasons change their aspect, and are unfavorable. Thousands have paid a heavy price for the experience by which this lesson has been learned, and no longer trust to a single crop.

Draining is a most efficient regulator by which to counterbalance in some measure the effect of wayward seasons. If there be too great rain-fall, the water speedily finds an outlet from the roots which it would otherwise drown. If drouth occur, the porous soil is enabled to draw moisture from beneath, and also condense it from the air which can enter from above. Corn on a well drained field will pass safely through a soak or a drouth which would diminish, by one-third, the yield from an undrained compact soil. Frequent stirring of the soil, keeping it loose and light, is of paramount importance, especially in drouth. The rapid evaporation which goes on at the surface under such circumstances, cools the adjacent air, and causes it to deposit copious dew, and moisture from below will also be drawn upward to supply the wilting plants. If in addition to this, mulching be practicable, to prevent the too rapid escape of moisture, drouth may be resisted, for a lengthened period. This may be done in the garden and fruit yard, and to some extent in the corn-field, where straw or refuse hay is plenty.

It is less easy to keep grass lands in heart during drouth, and other measures should be resorted to where the stock of cattle is large, and the amount of pasture and meadow only just sufficient to carry them through a favorable season. A field of corn or millet should be sown the present month, to be cut and fed green in August and September. The latter plant resists drouth even better than corn, and an acre will yield a supply for several head of cattle during the period when drouths are most frequently injurious to pastures. There need be no loss, if the crop be not wanted to supply Summer deficiency. A feed from the soiling patch at night will make itself felt in the milk pail in the morning, and what can not be profitably used in this manner can be cured and used to advantage in Winter. There is always less difficulty in disposing of superabundance of feed, than in eking out a short supply, and the wise husbandman will endeavor to err on the safe side, if at all.

Cultivating Orchards.

It is a question much discussed of late, whether or no orchards should be plowed and manured and cropped. We have seen orchards both old and young, cultivated to their injury. If an old orchard is plowed deep, it is quite sure to tear up and break the roots; and this will be followed by blight and stunted growth. If a young orchard is plowed carelessly, not only will the roots of trees be injured, but the bark will be bruised by the whiffletrees, and the trees themselves be gnawed and trampled on by the horses. An old orchard can be plowed shallow, and little harm come from it; but as a general rule, the plow should be kept outside of its boundaries. If the land needs enriching and re-seeding, scarify the surface with a harrow, and give a dressing of old manure, scattering the seed where it is wanted.

A young orchard not only can be plowed safely, but it absolutely requires cultivation. One might about as well throw his young trees into the street at first, as to set them out in tough sward, and let them so remain. Perhaps most of them will manage to live, but they can not thrive. Plow the land properly, manure it well, keep the surface hoed clean of weeds and grass for six feet around every tree, and it will make more progress in one year, than a grass-bound tree would in three or four. This is no mere speculation; the experience of every year proves it. As the trees become large, and the roots ramify, let the plow be gradually withdrawn.

The Scale on Apple Trees.

Mr. Hardy, of Chenango Co., N. Y., has sent us a specimen of apple tree bark completely covered with the scale insect, and numerous other readers of the *Agriculturist* have written us concerning its depredations upon their trees, asking for a remedy.

The insect is believed to have been imported from Europe, and is especially troublesome at the West, the section from which most of our complaints are received. The figure will give an idea of the appearance of the insect at the present season. The natural size is from 1-10th to 1-8th of an inch, and they are frequently so numerous as to cover every portion of the trunk and limbs. The shape of the scale is so much like that of an oyster that it is sometimes called the "Oyster-shaped Bark-louse." It is known by Entomologists as the *Coccus conchiformis*, and *Aspidiotus conchiformis*, the specific name—*conchiformis*, meaning shell-shaped. These scales contain the female, which dies after depositing her eggs. The eggs, which may be seen by carefully lifting the scale, are hatched late in May or early in June. The young insects are very minute; they move about for some days and then settle down and insert their proboscis or sucker into the bark, from which they draw their sustenance, and acquire their hard coat or shell. The females never leave the shell, but the males come out as small flies and have wings. These being, in brief, the habits of the insect, it will be seen that they can only be successfully destroyed soon after they are hatched, and before they acquire their hard and impervious scale. Various preparations have been recommended for their destruction; Harris advises the use of two parts of soft soap

with eight of water, to which lime enough is to be added to bring the mixture to the consistence of whitewash. This is painted over the trees early in June, covering every limb and twig as far as possible. Mr. Kimball of Wisconsin, trims the trees thoroughly and then applies, with a paint brush, a mixture made by boiling leaf tobacco with strong lye, until it is reduced to a pulp, and then mixing with soft soap to form a paint-like compound. Mr. Smith, of Connecticut, uses a decoction of tobacco, aloe and soft soap, applied with a syringe. Prof. Glover, of the Agricultural Department at Washington, informs us that he succeeded in destroying a similar insect upon the Orange trees in Florida, by syringing them with a wash of soft soap, water, and a little guano. Another says that the use of mackerel-brine will prove effectual in destroying them. This insect has its natural enemies which destroy great numbers of them, still its increase in some sections is alarming; it needs vigilance and care just at the right time. We would thank any of our readers who have had success in exterminating the scale, to give us their methods and the results.

How to Raise Peaches.

It is a well known fact that peaches do not succeed as well as formerly. In addition to want of fruitfulness from the unpropitious seasons, the borers and yellows are making great havoc in many sections. Timely care and faithful labor will clear the trees from borers, but the "doctors" have not as yet found an "infallible specific" for the yellows. Of one thing, however, observing cultivators are pretty certain, namely, that the disease is perpetuated by planting pits from unhealthy trees; and that too many nurserymen use no discrimination in the selection of seeds, we have evidence in the barrels of pits of all kinds collected in the streets of this city, and sold to planters. For aught the nurserymen know to the contrary, nine tenths of these pits were from unhealthy or diseased trees. To such, and to all who wish to raise their own trees, we commend the following from the pen of Hon. Wm. Parry of New-Jersey, in the *Hammonton Farmer*.

"The peach tree does best on new land, and seldom if ever will yield a crop where peach trees have grown before. There are trees on the light, new lands of Atlantic Co., N. J., over fifteen years of age, in a flourishing condition, bearing annual crops of fine fruit. The proper method of raising such trees is to save seed or pits from trees which are perfectly healthy, free from yellows, borers, and all other defects that would tend to weaken the constitution of the parent stock. The pits should be planted in Autumn, and covered with two inches of sand, so as to allow them to freeze and thaw during the Winter. In the following Spring, about two thirds of them will open their shells, and the kernels may be picked out and planted in mellow land suitable for corn or potatoes, in rows four feet apart and six to eight inches in the row. They should be kept clean and well cultivated until the latter part of Summer, when they are in a suitable condition to bud with desirable sorts, selecting buds from healthy trees.

The young trees should be left to grow one Summer after budding, in the nursery rows, and the next Spring be set out on good mellow soil prepared as for corn, which crop may properly be grown among the trees the first year after setting out. In planting the trees, mark out the land in squares, twenty feet each way, by

running a light plow through, and set a tree at each crossing. Dig the holes twice as large and twice as deep as would just receive the roots in their natural position. The roots should be carefully examined, and all bruised parts cut smooth with a knife, drawing it from the under side out. The yellow subsoil thrown from the bottom of the hole is not to be returned around the roots, but mellow surface soil must be filled in and packed closely under and over the roots, so as to prevent any cavities remaining.

An orchard thus carefully set out must not be neglected. The ground should be kept mellow and clear of weeds by frequent stirring, the suckers and surplus branches trimmed off, and the ends of the most vigorous limbs shortened in so as to give a more compact head. If gum should be seen oozing from the stem near the ground, take a knife and remove the little intruder that is preparing to make its winter lodging under the bark.

Plant Evergreens.

No grounds, however limited, should be without evergreens, which are beautiful in Summer and indispensable in Winter. The latter part of May is usually the best time for planting, though the backwardness of the season will this year extend the time well into June. Indeed, with a little care they can be removed during the early part of June in any ordinary season. Recent introductions have increased the list of varieties so enormously that one is puzzled, in looking over the catalogues of the nurserymen, what selection to make. Most of the recent importations bear a high price and their hardness in our climate is yet to be tested; and our advice is to leave experiments to those who can afford it and to stick to the old and well established kinds which are always satisfactory and can never become too common. The two evergreens which, from their ease of culture and intrinsic worth, are most popular, are the Norway Spruce and the Arbor Vitæ. They are easily transplanted, of rapid growth and, when well shaped specimens are chosen, are fine for the lawn and excellent for masses and screens. They will live in poor, and thrive in good soils, and will bear cutting as the cultivator may fancy. Nothing is more beautiful than a well grown specimen of our common White Pine, or Weymouth Pine, as it is called. The chief obstacle to its general introduction seems to be its nativity. If it were brought from a distance and sold at a very high price, it would be more generally sought after. Then there is the common Hemlock (*Abies Canadensis*), than which few evergreens are more beautiful. It is unfortunately rather impatient of removal, but it is worth while to take special pains to secure so fine a tree. The Austrian, Scotch, and Cembrian pines make noble trees, and the Pigmy Pine (*Pinus pumilio*) and the Irish and Swedish Junipers are desirable for small grounds. At any time, and especially in late planting, the greatest care should be taken to prevent the roots of evergreens from drying. They should be kept well covered from the moment they are out of the ground till they are replanted. Where it is practicable, the holes should be prepared beforehand, adding peaty earth if the soil is of a sandy character, and then wait for a cloudy day upon which to take up the trees from the nursery. Large stones laid over the roots are better than stakes; besides holding the tree in place they will act as a mulch to prevent the soil from drying out.

Basswood Bark for Tying.

Every nurserymen and gardener know that the Bass or Russia matting is the best possible material for tying up plants, binding buds, and many other purposes. The Russia article is frequently scarce, and is always difficult to procure by those who live far from cities. The want can be readily supplied from our native Basswood or Linden which is abundant throughout the northern States. Young and vigorous trees should be cut down during the present month and the bark stripped off. This is to be put into a stream or pond of water until the inner bark is readily separable in layers, which will be in two or three weeks. When the bark parts readily, it is to be taken from the water, carefully separated, a layer at a time, and then washed to free it from mucilage, and dried. There will be found a considerable difference in the strips. The finest should be selected for tying buds and other delicate work, and the strongest and thickest left for coarser purposes.

A Perfect Hedge.

A perfect hedge is seldom seen in this country. Our people are in too much haste to see results, too impatient of the needful labor and cost, to build up a good, durable hedge, one that will turn cattle, and be a real ornament to any farm or residence. Consider, a moment, the conditions of such hedge building. The line must not run beneath the drip and shade of trees, or among their roots. The land must be good, or be made fertile by manure. The plants should be properly set out, the ground tilled and kept free of weeds for several years. And yet, how few enrich and cultivate soil along their hedge-rows, after the first year! Equal in importance to this, is thorough and systematic pruning every year. The majority of hedges are allowed to grow up several feet before they feel the shears at all. Of course, they become lank and bare at the bottom, where they ought to be bushy and strong. They are shaped more like the letter V, and must always remain so, while they ought to be more like that letter inverted, Δ . They should, from the start, be cut back every Spring to a foot of the new growth: i. e., the hedge should be allowed to gain in height only one foot each year. The sides should be slightly trimmed, by all means keeping the lower branches broader than those above. The pruner should always keep in mind what the final shape of the hedge is to be. The inverted Δ seems to us a little too sharp, and we should advise rounding the sides a little, making it resemble a straw bee-hive, or rounded cone.

After the hedge is brought to its required height, say of four to six feet, it must be pruned at least once in mid-summer, to check its growth. Now, there are only a few persons who will take all this trouble, and this is a sufficient reason why we see so few good hedges.

Another reason lies in the defectiveness of our hedge-plants. The English hawthorn, so excellent in that moist and equable climate, does not generally succeed with us. Several of our native thorns have been tried, but where the hedge becomes full grown, and it is necessary to summer prune it, the leaves turn yellow and the plants become sickly. In a few sections, as about Wilmington, Delaware, the Cockspur is reported as doing well. The Osage Orange answers a good purpose south of the latitude of about 40°, but is not sufficiently hardy at the north. The Three-thorned Acacia is now

being extensively tried. It is hardy and thorny enough, but as it is a very rampant grower, it is by no means certain that it will bear the severe summer pruning necessary to keep it within bounds. And would our busy farmers find time to do that work? The Buckthorn comes the nearest to being a perfect hedge-plant in all respects but its thorns. It is hardy, not over-rampant in growth, for, unlike the Locust, it is a *bush* rather than a *tree*, bears shearing well, and is subject to no diseases or insects. It will answer for a strict barrier, if one will take the trouble to set a low and light wooden fence on the exposed side, made of only a single board, four or five inches wide, running from post to post. Paint this board green, and it will hardly be noticed. The White Willow is now creating quite a sensation at the West. Whether it will make a perfect hedge, is yet quite uncertain, but time and experience will determine.

The Best Native Gooseberry.

This is the Houghton Seedling. It is not of the first class, as compared with the foreign sorts, but it is the best American, seldom mildews, is hardy and prolific. Its origin is interesting. Some thirty years ago, Mr. Abel Houghton, then of Lynn, Mass., set out in his garden four of the best English sorts in a circle, with a native variety in the center. They all flowered and fruited the second year. He sowed the seeds indiscriminately, and where the plants came up, he transplanted them by the hundred into rows. In five years, they came into bearing, but nearly every one suffered from mildew. He saved the best and threw away the worst, and finally the sort known as Houghton's Seedling was the only one which proved worth saving and propagating. All honor to Mr. Houghton. Honor, indeed, he should have, for it is said that he has made no money by his long experiments.

Strawberries.

This is the harvest month for strawberries, and the time when the fruit is in perfection is the proper one in which to plan for new beds. While to many, one strawberry is as good as another, those of larger experience know that this fruit presents a great variety, not only in flavor and relative sweetness, but in the size and hardness of the fruit and the vigor and prolificness of the vines. The best berry for the table is not always the best one for the market; firmness of flesh and abundant bearing are for this purpose the most important qualities. Though we may have many very fine varieties, perfection is not yet attained, and every year there are new claimants to superiority over old varieties. It is no doubt possible that the efforts of cultivators will yet produce a fruit which will combine all the excellences of the best known varieties. Now is the time for those who intend to plant in the coming Autumn or Spring to visit the grounds of cultivators, or fruit exhibitions, and make observations for themselves. We expect that the exhibition which will be held at the office of the *Agriculturist* will present the finest collection of strawberries ever seen in this country, and those who attend it will derive much information. We shall publish some reports of the discussions of strawberry growers upon the merits of the different varieties, for the benefit of those who cannot attend the exhibition and the meetings.

The *Strelitzia reginae*.

A fine specimen of this old but little known plant, from E. Janes, Esq., of East Morrisania, N. Y., has been on exhibition for some weeks at the office of the *Agriculturist*, where its tropical looking foliage and very curious flowers have been admired by a throng of visitors. The plant is about 3 feet high and has four strong shoots, one of which has been figured by our artist. The *Strelitzia* was first introduced into England from the Cape of Good Hope nearly a hundred years ago. Its name was given to it in honor of the wife of George III., who belonged to the house of Mecklenburgh-Strelitz. The plant belongs to the same family as the Banana, and its leaves resemble those of that plant, though they are much smaller. The manner of flowering is very singular; a long green sheath is borne at the end of the flower stem, this bends to a horizontal position, and from a slit in its upper side the flowers rise one after another. From their gay color and peculiar shape, the plant is called by some the "Bird of Paradise."—The three under portions of the flower are of a golden yellow, and the narrow or central part is purplish blue. Each flower continues for several days, and is succeeded by another which rises out of the sheath.

For a long time it was cultivated as a hot-house or stove plant, but it is now found it will grow well in the green-house or as a house plant, as it will live in any room, where it is protected from frost. The objection to its general introduction as a house plant is the slowness with which it is propagated. It is multiplied by suckers which it throws up very spar-

ingly, and by seeds which are only formed by artificial impregnation of the pistil. It will grow in any good soil and should have a period of dryness and rest after flowering.

Arranging Bouquets.

We have letters from several correspondents asking us to give directions for the arrangement of flowers in bouquets. As this is a matter that depends so much upon individual tastes, it is difficult to give any precise directions, though there are a few general rules which may be followed. The beauty of a bouquet depends upon its form and color. The regular bouquet makers seldom use flowers upon their own stems; the separate flowers are each fastened to a splinter of broom corn by means of a bit of fine wire. Thus furnished with a strong and elastic stem, the flowers can be made up with greater ease than when upon their own stems. Bouquets made in this way are of course not benefited by placing them in water, but they retain their

freshness in a remarkable manner if occasionally sprinkled. A light and graceful appearance should be given by means of little sprigs of small flowers which should project beyond the general surface. A general fault in bouquets, is a deficiency of green; all flowers appear better in contrast with foliage. The Ground Pine (*Lycopodium dendroideum*), is one of the greens most used by the bouquet makers. Sprigs of asparagus are used with very good effect; any good green that does not readily wilt may be used. In regard to colors, the laws of contrast must be observed. A bouquet made entirely of yellow, red, and orange colored flowers would not be pleasing, for these are all harmonious colors. White flowers are very useful as they contrast with every other color. Red and blue do well together, while the effect of purple is weakened by either of them. Yellow and blue should be contrasted with white rather than with strong green. Neither red nor yellow should be put near orange. A little practice will enable one to combine the colors in the most effective way.

—0—

VINES IN THE FLOWER GARDEN. The introduction of vines and climbing plants into a garden gives it a gracefulness and variety which can come from no other method. By this plan, we not only have the ground covered with verdure and bloom, but the air also is filled with them. It is surprising to note what pleasing effect may be produced by simply setting up a few cedar poles, 6 or 8 feet high, and covering them with some common vines, like the

Morning Glory, of different colors. Set two or three within a few feet of each other, and extend stout cords from the top of one to the other. The vines will cover these cords and hang down in graceful festoons. Instead of poles, one may make ornamental frames or arbors, and cover them with a great variety of vines. The result will be every way satisfactory, and the whole need cost little time or money.

Plants with Variegated Foliage.

For a long time the striped or ribbon-grass of our grandmothers' gardens was the only variegated leaved plant in common cultivation, but now we have, under the rather absurd name of "foliage plants," a great variety, some of which are very beautiful. Many of the rarest ornaments of the green house are prized for their foliage rather than their flowers and we have annuals, perennials, and shrubs, and even trees the leaves of which are either wholly or in part of some other color than green. Japan seems to be very prolific in plants of this kind, and we have from there recently a Honeysuckle, an Arbor Vitae, and a Ginkgo with variegated leaves. Among the bedding plants of this character, *Coleus Verschaffeltii* takes a very high rank. We give below an engraving of a young plant, but it is impossible to properly represent its beauty without the use of colors. The leaves are pleasingly variegated, the lighter portions being of a tender green, while the markings are of a rich maroon or brownish purple color. This most desirable ornament to the flower border is to be had at the large horticultural establishments, but as yet bears a high price. From the ease with which it grows from cuttings it will doubtless before long be very abundant and cheap. Among annuals, the *Amaranthus tricolor* and *Perilla Nankinensis* are well known. *Amaranthus melancholicus ruber*, a new blood red

COLEUS VERSCHAFFELTII.

annual from Japan is highly recommended. A bed of these presents a striking appearance when viewed from a little distance.

About Ginger.

This is the root, or rather the under-ground stem, of a plant which is a native of the East Indies, but is now grown in many other tropical countries. The stem grows 2 or 3 feet high and is reed-like; the flowers are borne on a separate stalk, they are of a dark purple color, and appear from between broad scales, as is represented in the engraving. In order to save room, the artist has cut off the top of the leaf stem, and placed it by the side of the flower stem. Our supply comes from both the East and West Indies, and is imported in the root, which differs much in appearance and quality. When scalded as soon as it is taken up and dried in the sun it has a dark brownish color, but if the root is scraped before it is dried, it is much lighter colored. Some of the finer kinds are not only scraped but bleached, and are known as white ginger. The root is retailed in powder, and in the grinding is frequently adulterated with meal and similar substances, and several grades of ground ginger are kept at the wholesale stores at prices corresponding to the amount of adulteration. The preserved ginger, which is brought in jars from China, is prepared from the young and tender roots, before they have become stringy or have acquired a very powerful pungency. The fresh root is imported from the West Indies, and is frequently sold in cities for the purpose of flavoring citron-melon, and other preserves. These fresh roots which are usually brought in the Fall, may be planted in a pot and kept through the Winter, and in Summer be turned out into a warm place in the garden where they will flourish during hot weather.

Storing Butter under Ground.

A. Thompson, Pendleton Co., Ky., writes to the *Agriculturist*: "Last June I commenced packing butter. I washed it well through two or three waters when it was first churned, and worked it over again before I packed it, putting it in large stone jars, and digging a hole under the floor of the smoke house, having no cellar or other good cool place. The top of the jar was left just above the ground. I then put strong brine about two inches over the butter, pouring it off each time as I put in fresh but-

ter, adding nothing but salt to the butter, and in January last I sold 60 pounds of butter that was as sweet and good, as when first packed." To preserve butter in good condition the first essential is thorough working. A very small amount of buttermilk left, will soon taint the whole mass. When well worked and properly salted, it should be kept at a uniform low temperature. This was secured in the above instance by partially burying in a shaded place. Some other location than a smoke house would usually be preferable, as butter quickly absorbs any odor from surrounding substances. A small building would pay, where much butter is to be stored. A great gain will be realized by selling June made butter at January prices.

Which are the Best Milk Pans?

The following experiments lately made at the Munster Agricultural School Farm in Ireland, to determine the effect of various materials used for milk pans, upon the yield of butter, are given in the London Agricultural Gazette. The pans selected were of five kinds, viz.: glass, earthenware (black glaze), delft (white earthenware), tinned iron, and wooden vessels. In order to carry out the experiment with the greatest accuracy, the feeding of the cows was changed, and the temperature of the dairy varied at each experiment. The milk as it came from the cows was strained into a large vessel, and then measured accurately into the pans. The quantity of milk set in all cases was 8 gallons, and the cream from this, ranged from 5 to 6 pints. One week was allowed to elapse before the next experiment was commenced. In all, four experiments were made. In the first experiment the feeding was of a rich nature, and a large produce of butter was expected, and the temperature of the dairy was high for the season, viz., 55°. The feeding consisted of White Turnips, Swedes, Rape-cake (3 lbs. to each cow per day), grains, and hay. The expectation of a large yield of butter was realized, as two of the vessels gave the highest produce—3 lbs. of butter from 8 gallons of milk. In the second experiment the temperature of the dairy was lowered to 48°, and the feeding was Aberdeen Turnips, Swedes, grains, and hay. In the third experiment the temperature was raised to 50°, and the feeding was Mangels, Swedes, Aberdeen Turnips and hay. The temperature was 52° in the fourth experiment, and the feeding was Mangels, Swedes, grains and hay. The produce in butter is shown in the following:

Milk vessels	Experiment No. 1.	Experiment No. 2.	Experiment No. 3.	Experiment No. 4.	Average of the four experiments
	lbs. oz.	lbs. oz.	lbs. oz.	lbs. oz.	lbs. oz.
Glass	3 0	2 10	2 12	2 14	2 13
Earthenware (black glaze)	3 0	2 10	2 12	2 14	2 13
Delft	2 14	2 8	2 10	2 12	2 11
Tinned iron	2 14	2 8	2 10	2 12	2 11
Wood keelers	2 4	2 4	2 6	2 7	2 5½

It will be noticed that the yield of butter was varied by change of feed and temperature, but that the superiority of the glass and glazed earthenware was maintained throughout. The milk in wooden vessels was less affected by temperature, wood being a poor conductor of heat. The milk soured first in the wooden keelers, and in the delft and tinned iron vessels a few hours sooner than in the glass and glazed earthenware. The longer milk is kept sweet, the more time there will be for the cream to rise unobstructed by coagulation. The pores

of wooden vessels in time are more or less affected by moisture and acidity, according to the pains taken to cleanse them, and this hastens the souring of the milk. They can not be kept as clean as tinned iron or glass. The latter material in the above experiments gives about 5 per cent more butter, than the tinned iron, and 18 per cent more than the wood. The heaviness and brittleness of glass and earthenware are objectionable, and the loss from breakage would probably counterbalance any advantage gained in increased quantity of butter. The tinned iron pans in common use in this country, are, all things considered, the most convenient vessels yet brought into use. But for the expense, the best vessels would be porcelain lined iron ware, such as are used for preserving kettles. It may be a question whether the great durability of these vessels, as well as their effectiveness, may not make them the cheapest in the end. The annual interest would not amount to five cents each, per annum.

An Improved Dish-Pan.

A Western correspondent of the *Agriculturist*, "Bay," sends a sketch of the household implement shown below with the following description and remarks: "Diameter of the pan lengthwise of top, 19½ inches, at the bottom 15 inches; short diameter of top 15½ inches; of bottom, 11½ inches; depth of pan 7 inches; handles 2 by 4 inches. My mother, a good housekeeper after the English pattern, always considered it a lady's bounden duty to wash up the breakfast dishes herself, thereby making sure each day that her china-closet was in order, that none of the silver was missing, or glass and cutlery strayed into the kitchen. This operation is facilitated by such a pan as I describe; having divisions,

one for washing, the other for draining: it can be used without slopping, and obviates the necessity that exists in some families, of having dishes carried to the kitchen and back, after each meal. This not only saves time, but risk of breakage, as well as insuring a wholesome division between dining-room and kitchen table articles." [A dish-pan of the above dimensions, would seem to be too small for both washing and draining divisions, unless for a family of only two or three persons, and using but few changes of dishes.]

To Keep Bed Clothes on Children.

Many a severe cold, and not unfrequently sickness and death, have resulted from sleeping without covering; and this happens quite as frequently in Summer as in Winter, for in the latter season, greater care is exercised, and the windows and doors are less likely to be left open in a way to produce a direct draught of air. Restless children will throw off the clothing, notwithstanding the final visit to their beds by the careful mother or father, before retiring. This can, in part, but not wholly, be prevented by light suppers of simple food, taken early enough to be in part digested before going to bed, which is always advisable. No one, young or old, can sleep well with a poultice of *hearty*, undigested food on either the outside or *inside* of the stomach. In addition to the above, we have for several years successfully practised fastening the

covering upon the bed. For this purpose, simple screws, or small wooden knobs, fastened into the two side rails on the under side—one near each head post, and one near the foot. Two strong tapes or narrow strips of cloth are tacked across one coverlet a few inches from the head and foot, and loops on the ends are brought over the side rails, and thrown over the screw-heads, leaving the coverlet loose, but so that it can not be pushed off. The long strip is preferable to short loops fastened to the edges of the coverlet, which may tear out. This method is effectual, and costs but little trouble. In a letter to the *American Agriculturist*, "Ann Eliza," of Cold Spring, L. I., writes on the same subject: "To make a child sleep comfortably, and not push off the bed clothes, screw a small knob on the side of the trundle-bedstead or cradle, on the inside, then sew strong loops or strings, on the under quilt far enough from each end, to draw it snug across under the chin, not too tightly; then, put on as much other bedding outside as is necessary, and so long as the loops and knobs do not give way, the child can not get uncovered. If a child has the habit of throwing the head back, and pushing itself out in that way, slip down inside the head board, another peg high enough to go 10 or 12 inches above the pillow; or better still, if the trundle-bed is drawn out before a door or window, have a head similar to a cradle head, to slide down far enough, to set firmly on the bottom of the trundle-bedstead, and the child can not help sleeping warm. If for two children, put a middle loop on the quilt, and a knob in the center at the head. The knobs should be far enough down so that they can not strike the head against them, and the loops long accordingly. In very cold weather the child's bed should be warmed, by laying in the bed pieces of wood or board, that have been previously warmed in the stove oven, putting in half an hour before the child goes to rest, so that not only the blanket but the bed will be warm; and the little ones will not be shivering a long while, but nestle down and in a few minutes be fast asleep. The two children of the writer sleep, one in the trundle-bed, and one in the cradle, fastened as above described, and have never known what it was to sleep cold. None but a mother can know what a satisfaction it is, to be certain that her child is comfortable in a cold Winter night, and no fear of throwing off the covering, and laying the foundation for a fit of sickness, and perhaps death."

Refrigerators—Economy in Ice.

Ice is not merely a luxury but almost a necessity in the household, and in this season of scarcity, the greatest economy should be exercised in the use of it. Great improvements have been made in refrigerators or ice chests, within a few years. In the old box refrigerator, where a lump of ice is put at the bottom, and the articles to be cooled placed over it, there is an unnecessary waste of ice. The provisions in this are cooled only by giving off or radiating their heat which is absorbed by the ice, and they, being at the top, are always in the warmest part of the refrigerator. In several recent inventions the ice is placed at the upper part of the refrigerator and its contents are not only cooled by radiation, but also by a descending current of cold air which is passing over them. This current can not take place when the ice is below. We have upon our Exhibition Tables a model of a "Polar Refrigerator," which has some excellent points. The box is divided into two compartments by a central ice chamber. This is made of corrugated zinc, and wedge shaped with the larger end uppermost. The ice is placed at the top of this chamber upon a rack, and the water, which results from its melting, and which is still very cold, is retained in the lower part, where it can be drawn off for drinking. It is an advantage to have separate compartments in the refrigerator, as delicate fruits, butter, milk, etc., can be kept where they will not contract any unpleasant flavor from meats and other provisions. In the use of ice for cooling drinking water, a great saving is effected by

the use of double ice pitchers. These are two metallic pitchers placed one within the other, and the intervening space filled with some non-conducting material. In cooling water in the ordinary way, we often use ice very wastefully. A pound of ice in small fragments will cool more than three lbs. of water from the ordinary Summer temperature, to 32° or ice-cold. It is not necessary to reduce the temperature of water so low as this, it being too cold either for comfort or health, and a much smaller quantity of ice than is generally used by most persons will make the water pleasantly cool.

How to Fasten Corks.

It is often very desirable to confine the corks of bottles more strongly than can be done by merely sealing them with wax. In bottling cider, sparkling wine, etc., the gas evolved exerts a very strong pressure, sometimes sufficient to burst the bottles, and the cork is easily forced out, if not tied down. Wire is sometimes used for this purpose, but stout twine properly put on, will be sufficient. The illustrations show quite plainly

Fig. 1.

the manner of doing this. A simple knot is first made, (Fig 1.), and the loop drawn upward to pass over the top of the cork. It is then placed around the neck, just below the projection, drawn tight, and the two ends are brought up over the cork, when it can be readily tied, as shown in Fig. 2. If preferred, fine flexible wire can be used in the same way. This may seem like a small matter to illustrate, but we consider nothing as unimportant which may prove of convenience to the housekeeper. We may here add what has often been stated, that we are always pleased to receive such suggestions and hints of contrivances which may not be generally known to young housekeepers.

Fig. 2.

"Splendid Jewelry!"

The above words head an attractive advertisement, recently published in this City. The articles offered are said to be made of "the celebrated Oreide Gold," which "has been found to work equal to pure gold. In finish and beauty they are equal, if not superior to the genuine article." Following this is a price list, from "Gold" watches at \$10, down to "Gold" studs at \$1. This is an attempt to obtain money under a wrong coloring. Oreide Gold, as it is called, is a cheap alloy of copper and zinc, worth little more than brass, but capable of longer retaining a bright polish. In appearance it somewhat resembles gold, but will ultimately tarnish like any base metal. So good is the imitation, however, that thousands of dollars have been realized from the sale of articles made from it. At first they were represented to be fine gold, and were distributed by "Gift Enterprise" establishments, until that game was played out. Now the attempt is made to palm off this cheap compound under a deceptive name. Fortunately the community have been somewhat enlightened as to the probability of obtaining a dollar's worth of goods for a few cents, and the swindle will probably not be abundantly successful, at any rate, not among the readers of the *American Agriculturist*, we think.

The cheap jewelry manufacturers have much to answer for, not only on account of the deceptions

practised in the business, but because of the incitement given to a love of display, which was already a sufficiently prominent national characteristic. Young persons now-a-days are seen glittering with shining ornaments, which might provoke the envy of the Squaws of our Western wilds, or the untamed negroes of Central Africa, but which only excite disgust in the minds of persons of good taste. There is no rational objection to personal adornment. The Almighty intended man to be the most beautiful of all earthly creations. But the addition of a profusion of shining metal, or sparkling stones is no improvement to beauty. A plain ring, a neat pin, or some inconspicuous ornamental keepsake may be admissible, but any jewelry or other articles which attract attention from the wearer, thereby demean him into a mere walking show case for the manufacturers' wares. No trinkets can make a homely face beautiful, but modesty, patience, kindness and all virtues will add charms of surer and more lasting attraction.

For the *American Agriculturist*.

How to Polish Shirt Bosoms.

I was somewhat amused by the letter from a young housekeeper, Mrs. Pry. As she feels desirous to make her husband's shirts, bosoms and collars look nice, I will endeavor to tell her how my wife does up mine. The first thing is to wash them clean, then starch them thoroughly with the best of starch. A little pure spermaceti or dissolved gum arabic in the starch will improve it, but have the starch thick, and work it into the linen thoroughly. When in a proper condition, use the common sad iron to smooth them, and get them in proper shape, the same as though they were not to be polished, I would here say that you can not polish linen on a soft cloth. Take a piece of hard wood (I use birch) say 10x14 inches, or size of a shirt bosom, and plane it even and smooth. When you use the polishing iron lay the linen on that, without any cloth underneath; a liberal supply of elbow grease is indispensable to make the things look first-rate. Now for the polishing iron. We use McCoy's Patent. I have seen several kinds, but I like this the best. You can not polish with an iron with a flat face; the one I use is made something like a small shoe, with a round heel on both ends, nicely polished, and care should be had to keep it so, if you wish to have your linen look well. The linen we buy at the stores, is polished by men, or machinery, which gives it a finer polish than can usually be given by females. But if Mrs. Pry will get a good polishing iron, and follow the directions as given, she will not feel ashamed of her husband's bosoms and collars.

Cumberland County, Me.

BENJ. FURBISH.

"What to Do with the Rats?"

In answer to this question in the April *Agriculturist*, I would say, do as a friend of mine did when he found his newly-purchased house and stable infested with these destructive animals. Mix equal quantities of plaster and Indian meal, and put where they can get it, and they will devour it greedily. It will make them thirsty and they will seek water, which brings on an indigestion. My friend found them, in the morning, lying in heaps by the gutters. In the country it would be well to put water where they could get it easily, so that they need not rush to the wells. This appears to be the safest and most effectual way of managing them.

Westchester Co., N. Y.

E. D. REED.

[Plaster is wholly inert, and if useful as a rat destroyer it must act mechanically, by hardening into lumps inside the "critters," and of course the burned plaster such as is used by stereotypers, plasterers, stucco workers, etc., must be fed with the meal. If the rats will eat enough of it with meal, to make a respectable boulder inside, it will probably be effectual. Plaster is cheap and can be easily tried. The common ground field plaster will not harden with water.—This rat remedy reminds us of the great stories told "out west," when plaster first came into

use. It was said "that a person riding by a house early one morning, discovered a pair of enormous legs and feet hanging out of the window. On inquiry, it was found that some plaster had accidentally been mixed with the flour for tea biscuits. The 'fertilizing' effects were so great that the man had, during the night, *grown* so fast as to have his legs extend through the windows and bending down at the knees, his feet touched ground." They would probably have taken root but for the disturbance of the early passer by! This is a fact of course—just as much so as one half the stories of the wonderful effects of many of the manufactured manures. Ed.]

To Put up Strawberries, etc.

We have had all Winter, and are still using, some of last year's crop of strawberries, in excellent order and flavor. They were chiefly kept in Potter & Bodine's Jars, the most convenient, and every thing considered, the best of the twenty odd kinds we have tried thus far. (Many patent jars promising well have cost us loss of time, fruit, and sugar, to find out that they were poor. The porcelain-lined iron jars are the best of all, but are rather too costly for general use, though possibly cheapest in the long run.) The best plan is, to fill the jars with strawberries, then pour in a syrup made by boiling $\frac{1}{2}$ lb. to 1 lb. white sugar in a quart of water. The jars are then set down nearly to their necks in cold or lukewarm water in a wash boiler, and the water heated to boiling. When the berries have had time to barely cook through, the jars are lifted out, and one is used to fill up all shrinkage in the others, so that they shall be quite full. Wipe the top clean with a damp cloth while they are still hot. The covers are then put on and fastened tightly. Set into the cellar or any cool room. We put up 144 quart jars last year, of different kinds of fruit, and only lost by fermentation two bottles of tomatoes. When the above, or other good jars, are not accessible, common junk bottles, thoroughly cleaned, or other glass bottles or jars, may be used, as we know by many successful trials. Tightly fitting soft corks, tied in, answer well for covers. It is best to make these surely air tight, by dipping the corks and necks when dry, but still hot, into a cement made by melting together an ounce of lard and about a pound of rosin. Simple beeswax, or grafting wax, will answer.—The fruit may be first cooked with a small quantity of syrup, in a porcelain lined, or even a tinned vessel, and then dipped into the previously warmed jars or bottles, sealing up as soon as the air bubbles have risen and their place is filled with more cooked fruit. This mode is more convenient, but does not preserve the shape and flavor of the fruit as well as the other way. The smaller the amount of sugar, the better will the natural flavor be preserved. We use just sugar enough to fit the fruit for the table.

The above directions answer for other berries, cherries, peaches, and for other fruits, except that pears, quinces, cherries, etc., require longer cooking to heat them through. Tomatoes need boiling down one half, both to save room and to make them keep well. The above method is infinitely better and cheaper than the old mode of preserving with a large and unnecessary quantity of sugar.

"That Squeaking Door."

"Careful! careful! Don't open that door; it squeaks [creaks] so, it will wake baby up."—This was what the writer heard when making a call, the other day, and what has been heard in a hundred or thousand other houses. Many mothers go on a whole year watching the creaking door, lest it "wake baby up," or disturb a sick one. It may seem a small matter, but Mr. Editor, please tell all such mothers that read the *American Agriculturist*, to take a few drops of oil in a spoon, or a little fresh lard, and with the finger rub a trifle upon all the door hinges at the points where they wear bright, and the creaking will be stopped for months at least. A minute's time on a door, will save hours

of time in watching it, or in getting the baby to sleep after being waked up. HOUSEKEEPER.

Vinegar from Clover

L. C. Cook, Saratoga Co., N. Y., sends the *Agriculturist*, the following as a substitute for good cider vinegar: Take 2 qts. red clover blossoms and 10 qts. of water, boil five minutes, strain, and add 1 lb. sugar, 1 pint molasses. Put it into a stone jar, and when lukewarm, add four tablespoonfuls of good yeast. Put 2 qts. more of clover blossoms on the top of the liquid, cover close, set in the sun, and in four weeks you will have a cheap and good article.

[Spent tea leaves, and indeed almost any kind of vegetable material will make vinegar, when mixed with sugar and yeast. The acetic acid, or vinegar, is mainly produced by the sugar, the yeast starting the acetous fermentation. The vegetable matter affects the flavor, and perhaps the clover blossoms may give a flavor pleasing to many persons. It will cost little labor or trouble to try it.—Ed.]

Directions for Curing Beef.

Contributed to the *American Agriculturist* by Joseph H. Alexander, St. Charles Co., Mo. "For 100 pounds of beef, take 10 lbs. salt, 4 ozs. of saltpetre, 1 quart molasses, 6 gals. water. Boil the mixture, skimming off the impurities; and having cut up and packed the beef in a tight vessel, pour the mixture on the beef hot, boiling hot. The beef is ready for use as soon as it is cool. Some recipes say take twelve lbs. of salt instead of ten, but from actual experience I have become satisfied that ten pounds will make the meat more palatable—being one pound of salt to ten pounds of beef."

Charlotte Russe Pudding.—Contributed to the *Agriculturist* by "C. E. M." Heat three pints of milk to near the boiling point. Stir into it the yolks of eight eggs, and one large tablespoonful of corn starch. Let it thicken a little, and sweeten and flavor to the taste. Lay slices of sponge cake in a pudding dish, pour over them the pudding, add to the top of it the whites of the eight eggs well beaten, set it in the oven and let it brown slightly, when it is ready for the table.

Rice Pudding.—Contributed to the *Agriculturist* by "E. F. S." Boil $\frac{1}{2}$ pint of rice in milk until soft; then stir it gradually, while still hot, into the well-beaten yolks of 4 eggs, and add 4 tablespoonfuls of sugar, and flavor if desired. Beat the whites of the eggs to a stiff froth, add to them 4 tablespoonfuls of pulverized sugar, and a little flavor, pour over the prepared pudding, and set in the oven until nicely browned.

Apple Pudding.—Contributed to the *Agriculturist*, by Mrs. M. E. Goodwin, Litchfield Co., Conn. Fill a dish $1\frac{1}{2}$ inches deep with sour apples pared and quartered. Spread over them a batter made of $1\frac{1}{2}$ cupfuls of flour, a little salt, $\frac{1}{2}$ teaspoonful of saleratus, and wet with milk (lipped milk is best), to make it as thick as the batter can be spread. Bake in a quick oven, and when done, turn it bottom upward on a platter, and sprinkle with sugar, or serve with any sauce.

Suet Pudding.—Contributed to the *Agriculturist* by "E. F. S." $\frac{1}{2}$ pint finely chopped suet, $\frac{1}{4}$ pint molasses, $\frac{1}{2}$ pint sweet milk, $\frac{1}{2}$ pint raisins, 1 tablespoonful ginger, 1 teaspoonful soda, 2 teaspoonfuls cream tartar, and flour enough to make it a little stiffer than pound cake. Boil two hours; eat with liquid sauce.

Mica Chimneys have been tried for lamps, but the smoke and dust collecting on or between the laminae soon render them opaque. But for this fact, they would be very valuable, as no amount of heat would break them.

To SWEEP CARPETS.—A Correspondent says: Mix corn meal with water to a stiff dough, and sprinkle over the carpet before sweeping. It re-

moves all dust so as to give a beautiful clearness to the colors.—We have seen the same "prescription" going the rounds of the papers—but it appears nonsensical. Unless mixed so dry and compact as to remain in lumps, the meal would sweep into the carpet, and literally bedaub it; while if not wet enough to moisten the fabric, how could it brighten the colors? Coarse tea leaves, swept along while moist, would remove the dust and lint, without soiling the carpet.—Ed. *American Agriculturist*.

BOYS & GIRLS' COLUMNS.

Answers to Problems and Puzzles

in May No. (page 151). No. 37. *Illustrated Rebus.*—"Man W ants butt little h ear below nor W ants T hat little l on G ;" or, Man wants but little here below, Nor wants that little long. No. 38. *Problem.*—Answer: Three small yards were made, one enclosing three, another five, and the remaining one, seven sheep; and a fence was then built around the whole three enclosures.—No. 39. *Arithmetical Problem.* Answer: A. dug 27.18 rods; B. 22.48 rods; C. 40.34 rods.—*Note.* By an error in the type the answer to the clock problem (No. 26) on page 151, was given as April 15th; it should read April 16th.

The following have sent in correct answers to recent puzzles and questions; the numbers indicate the problems answered by each. George Elcock, 33, 36; Wm. E. Hower, 36; Augustus Reifsteck, 35; W. New Puzzles to be Answered.

No. 40. *Illustrated Rebus.*—A true and pithy saying.

No. 41. *Illustrated Rebus.*—A very familiar proverb.

No. 42. *Mathematical Problem.*—Two men were equal partners in the purchase of 160 acres of land; the difference in quality was such that 60 acres on one side was equal to 80 acres on the other side. How many acres should each man have, allowing the quality of their respective shares to differ in the above ratio?

No. 43. *Riddle.* The answer should be full of sense.

I'm full of brains, yet never had a mind;
I'm higher than the greatest of mankind,
I daily lose my head for honor's sake;
Though often in a nap, no sleep I take.
At ease I rest upon the seat of power,
And to the ladies add a perfect tower;
Yet who can tell (for pride must have a fall)
How long my form shall be discerned at all.

ONLY A BUNCH OF ROSES.

Engraved for the American Agriculturist.

Roses are very common. You might find plenty of such during this month in your garden, or blossoming wild along the hedge rows, free for all who choose to pluck them. Notice now the little girl in the picture prizes them; how carefully she waters them. She values them because they are beautiful, without thinking whether they be scarce or plentiful. If some skillful artist had designed such flowers, everybody would be eager to possess them; the inventor's name and fame would fill the papers. Are they less to be admired because they cost little, and is the Creator, of such beauty to be less praised, because he gives them freely? He is rather to be adored because he has made beautiful things so common. The little girl has, no doubt, lately removed to the country, and the roses are new to her. In the crowded streets of the city she seldom saw a flower; she was too poor to buy them. Now she is rich—not in money, but in happiness, which is more than wealth. Do you often think how easy it is to be thus rich? Every boy and girl living in the country possesses what no money can buy in the city. There is pleasant food for the eye and the mind, as well as for the body, free to all. A single look across the green fields is worth more than the finest display seen in the streets of the largest city. It contains more beautiful, and more wonderful things to those who know how to observe them. How much better to use the means of enjoyment so freely bestowed, than to toil and sigh for the less satisfying pleasures invented by man, and to be had only for money. It will greatly increase the pleasure of examining such objects, if you have them under your own especial care. Every girl and boy should plant at least a few seeds and watch them as they grow day by day. You will find much help to properly observing them, by attentively studying the notes on "The Boys' and Girls' Garden" in another column. This will also teach you to be observing in other matters, and thus form one of the most useful habits. We desire that these pages, specially devoted to the young,

shall be to them not only a source of pleasure, but of improvement also. It is only a small part of our education that is received at school.—The engraving is interesting as the copy of a painting by G. H. Boughton, an American artist, now in England, and contributed by him to the sale for the benefit of the Lancashire sufferers.

We Believe in Fortune Telling.

"Do you believe in fortune telling?" asks a young correspondent of the *Agriculturist*. Yes, certainly, and practise it too. Would you like a few trials of our skill? Well, then, give attention. When a boy with black eyes and hair always tells the truth, he will be believed and respected as long as he lives, and as people would prefer to keep him alive, he will stand a good chance to arrive at old age. A girl with brown hair and blue eyes who obeys her parents, is good tempered and industrious, will have many admirers, particularly among sensible men, and she will therefore be in the way of getting a good husband. If a small boy with white hair and grey eyes will learn all he can from books and observation, will practise what he learns, think for himself, and work with energy, he may become both wealthy and wise. If a girl with rosy cheeks and curly hair will avoid late hours, tight dresses, too many nice things to eat, will take plenty of exercise in the open air, and keep good-natured, she will probably be a good looking and happy lady, and if she obtains a good education, she will be a fit wife for a Governor or President. In all these cases the hair and eyes are of no great importance, but the other requisites must be strictly observed to have the good fortune come out right. There! that kind of fortune telling is worth more than all the gipseys, seventh sons, wise women, astrologers and soothsayers could tell you from the time of the Witch of Endor, down to the year 2000. If you have any doubts on the subject, try following our directions, and see if we be not true fortune tellers.

Boys' and Girls' Garden—No. 3.

How does the little garden get on? Most of you, doubtless, have the plants well up by this time, and have compared their early growth with the account given in our last chapter. You have seen that there was already a little plant, or *embryo*, contained in the seed, and that this expanded and grew from the food which was provided for it beforehand. This small supply of food was soon used up, but not before the plant had made a few roots by which it could draw sustenance from the soil. Let us consider what your plants are doing: They are, like all other plants, engaged in taking up materials from the earth and air, and working them into their own substance—they are growing. Is it not wonderful that the little plant can build up fresh green leaves and, by and by, beautiful flowers out of the crude and shapeless matter supplied from the earth and air! The plant receives most of its nourishment by the root, which goes on branching and spreading underground in search of it. If we take up a plant carefully, Flax for instance, we shall see (fig. 10.) how the root is forked and divided up into little fibres. All that the plant takes up from the soil is dissolved in water, and the roots are made to expose great surface in order to take it up rapidly. The principal business of the root is to absorb moisture. All of the plants we have selected for our illustrations are *annuals*. That is they live but one year and, with the exception of the Four O'clock, all make these fibrous or branching roots. We have seen that the seed leaves or cotyledons in some cases serve two purposes—in the Melon, (or cucumber,) and Flax, they first hold the food for the young plant and afterward serve as ordinary leaves. In *biennial* plants, or those which live two years, the roots are made to do two different things. The first year, they absorb crude food from the soil, and after this has been prepared in the leaves, it goes back again to the roots where it is stored up for use the next year. The root in this case becomes very thick and fleshy as is seen in the beet, turnip, and carrot, which are all biennial roots. The first year they store up food and the second year they expend it in making flowers and seed. Where the root lasts through several years, as in our trees and shrubs, it is *perennial*. This is enough about the root for the present, though we may have to return to it again another time. Let us now look at the *stem* which, while the root has been growing and spreading below ground, has been lengthening above ground and doing its work, which is to hold up the leaves and allow them to spread to the light and air. The first growth from the seed was the elongation of the little stem or *radicle* which in the Flax, Morning glory, etc., lifted the seed leaves above the surface. A little bud soon appeared between them, which was lifted up by the lengthening of the stem, and, in the Flax, (fig. 10.) two leaves unfolded; above these the stem lengthened again and two more leaves opened, and so on. The increase in height of the plant being produced by a

continued lengthening of the stem, bearing pairs of leaves at intervals. We see that the growth of the plant since it started from the seed is but a repetition of its early growth. We had at the first the *embryo*, which was a little stem and a pair of leaves, and the plant has done nothing since but make little joints of stem and produce pairs of leaves. It will be noticed that the Flax and Four O'clock produce a pair of *opposite* leaves at each joint of the stem, while the Morning glory, (fig. 11.) bears only one leaf at each joint; such leaves are said to be *alternate*. The stems of our plants present considerable difference: while the Flax and others stand upright, the Melon will soon lie flat upon the ground and the Morning Glory will wind itself around a stick or some other support. Still, with all these differences, it is easy to distinguish the stem, and it is really the same thing and answers the same purpose, whether it is the weak stem of the Morning Glory that dies down with the Winter, or the woody stem of the apple or other tree that lasts for many years.—Now let us look a little at the leaf. This is a most important part of the plant, for here the crude liquids taken up by the roots are exposed to the light and air and fitted to be used in the growth of the plant. In the leaves much water is evaporated, and the breathing

FLAX.—Fig. 10.

of the plant is going on, and they are made to expose as much surface as possible. If we look at a Morning glory leaf, (fig. 12) we find first a leaf-stalk or *petiole*, and then the broad part or limb of the leaf. A strong rib—the *mid-rib*—runs directly through it from the petiole to the point, and from this numerous *veins* branch off on each side, so that the leaf when held up to the light, is seen to be a frame work of fibres, filled in with a green pulp. We find leaves having a great variety of shapes; some of them have petioles, but this is not essential. In the Flax there is no petiole, the blade sets directly on the stem, is *sessile* as it is called. The leaf of the Morning glory is *heart-shaped*. That of the Flax and Oat are *linear*. Many other terms are used to express the shapes of leaves, which need not be learned at present. The Tomato leaf (fig. 11) will be found very much cut up, and is what is called a *compound leaf*. These parts of the leaf are called

Fig. 11—TOMATO LEAF.

leaflets. If you notice other leaves, you will find a great variety in this division, from the deeply cut leaf of the Tomato, to leaves that merely have their edges notched like a saw, as in the cherry. In the Sweet Pea, (fig. 14,) the petiole bears two divisions or leaflets, and the end of the petiole bears a little appendage, as in the lower leaf in the figure, which is sometimes developed as a leaflet, as shown in the second leaf, but when the plant gets older, it appears as a tendril, represented in the upper leaf, by which the plant clings to brush or other support. Where the petiole of the Sweet Pea leaf joins the stem are a couple of little appendages called *stipules*—upon the garden pea these are very large. The stipules as well as the petiole are not always present. The leaf of the Oat, (fig. 13,) will upon examination be found to present a different appearance from the other. At first sight you will be puzzled to make out its different parts, but on close examination it will be seen that the *petiole* here is broad and clasps around the stem, forming a kind of sheath. Upon holding the blade of the leaf up to the light it will be seen that the veins are very different from those of the other leaves; instead of forming a net work they all run straight from one end to the other. It was mentioned in the last lesson that the embryo of the

Fig. 12—MORNING GLORY.

with netted veins, while monocotyledonous plants have no netted veins, but they are parallel, running lengthwise as in the Oat, or from a mid-rib straight out to the margin of the leaf. Of course we can not give all the varieties which leaves present, but they will be found to be constructed on essentially the same plan. Now if you have looked at the plants attentively you will have observed two things which it is well to bear in mind: 1st. That the same part may take on a great many different shapes and still perform its work. This has been illustrated in the different forms of the stem and leaf. 2d. That a part may be wholly or partly diverted from its ordinary use and made to serve another purpose. We have seen that the seed leaves may serve to hold food;

Fig. 14—SWEET PEA.

that the root, as the beet, etc., may also store up food, and that a part of the leaf may be modified, as in the pea, into a tendril to help the plant to climb. All the parts of the plant concerned in making its growth, are either root, stem or leaf, and having seen how these vary in those we have mentioned, you will now take great interest in looking at other plants, and in seeing what an infinite number of shapes can be given to these three parts.

HOW ARE OUR DRESSES TO BE MADE?—A contemporary answers the foregoing question in the following lively manner:—"By a sewing machine, of course. We trust that the day is over in which needle drudgery sets a feeble opposition to the musical click of the Wheeler & Wilson machine. A lady who says she does not know how to use a sewing machine, is looked upon with as much distrust as a lady who says she don't like babies! Side by side, in every home, we see the piano and the sewing machine. Of course, people have a right to their preferences, but give us the merry little musician whose crystal eye and silver tongue not only fill the ear with melody, but set the pulses of life and health throbbing anew in the weary hearts of a million women. Is it not better than all the pianos ever tuned? Some of the newest improvements to the Wheeler & Wilson machine, are the Binder, Braider and Corder, all of which ladies find indispensable. The Braider is particularly appropriate to the present mania for decorating everything with braid. "I do not know what we should do without the Wheeler & Wilson Braider," said the director of one of our fashionable mantilla establishments, when we inquired how those tasteful labyrinths of braid were laid on, and his words are echoed in every home in the land.—Really, we scarcely know which blessing to wish our young lady friends—a Wheeler & Wilson machine or a husband! We rather incline to the former, for they can exist minus the matrimonial alliance, but *can't* do without a sewing machine. What do you say, girls?"

From the New-York Evangelist.

EMBROIDERED DRESSES.—The fashion of having embroidery on cloaks, ladies' dresses, and, in fact, garments of almost every description, is rapidly on the increase in this country—imported, as are other fashions, from Paris. Fortunately for the ladies, the *crisis* has not caught them unprepared, and left them with no other means of ornamenting their articles of dress but the tedious and tiresome one by hand. There is at least one of our popular sewing machines (GROVER & BAKER'S) which is adapted to both sewing and embroidery—the latter as well and as rapidly as it sews the plainest sewing.

SNUG FARM FOR SALE.—70 acres with good House, Barn and Well—light soil, no stones, 5 1/2 miles from Saratoga Springs—Price \$1,500 including crops, stock and implements. Title unexceptionable. Enquire of CHAS. EDMONDS, 80 Nassau-st., New-York.

Fig. 13—OAT.

Oat was peculiar in having but one cotyledon, and we now see that the leaves are very different from those plants in which the embryo has two cotyledons. It is generally the case, that dicotyledonous plants have leaves

OFFICE OF

FISK & HATCH,**BANKERS AND DEALERS IN GOVERNMENT SECURITIES.****No. 38 Wall-st., New-York.**

AGENTS FOR THE SALE OF

THE UNITED STATES FIVE-TWENTY YEAR SIX PER CENT BONDS.

The interest on these Bonds is at the rate of Six per Cent. per Annum, and is payable 1st May and November, in GOLD. They are called "FIVE-TWENTIES," because redeemable at the option of the Government after 5 or within 20 years.

The *Coupon Bonds* are issued in denominations of \$50, \$100, \$500, \$1,000, and are payable to bearer, as are also the *Coupons* for the collection of the interest. The Registered Bonds are issued in denominations of \$50, \$100, \$500, \$1,000, \$5,000, \$10,000, and are payable to the order of the holder, and registered in his name on the books of the Treasury Department at Washington. The Registered Bonds have no Coupons attached for the collection of interest, but the interest may be collected by the holder in person, or by any person having his Power of Attorney for the purpose, at any Sub-Treasury of the United States which he may designate.

We sell the Bonds for the Government, both Registered and Coupon, in any of the foregoing denominations, at the rate authorized by Congress, without any additional charge for Commission, viz.: at PAR, and accrued interest, or at PAR, with interest commencing from the date of subscription.

NOTE.—The Bonds are issued to us by the Government at different periods, and bear interest from the date at which we pay for them, as indicated by a stamp on the first Coupon. For the few days intervening between their issue and the time of sale, we charge the accrued interest, payable in Current Funds. Or, if purchasers prefer it, we take their subscriptions, and ordinarily in two or three days thereafter, deliver them Bonds, bearing interest from the date of their own subscription and payment, with no accrued interest to be paid.

We are thus enabled to save parties all trouble and expense in finding Legal Tender Notes, or otherwise investing in these Bonds.

Orders or inquiries by mail will receive prompt attention, and the Bonds will be sent to any address, by mail or express, as desired. Payment may be made in BANK NOTES CURRENT IN NEW-YORK, DRAFTS AND CHECKS ON CITY BANKS, OR U. S. LEGAL TENDER NOTES. Persons in the country can send their orders and money to us direct, or call at the nearest Bank and ask the Cashier to do it for them. Drafts or Checks may be sent with safety by mail. Bank Notes or Legal Tenders should be sent by Express.

ON AND AFTER JULY 1, 1863, THE PRIVILEGE OF CONVERTING LEGAL TENDER NOTES INTO THESE BONDS, AT PAR, WILL CEASE, AND IT WILL BE NECESSARY FOR PERSONS DESIRING TO OBTAIN AT PAR A UNITED STATES BOND BEARING SIX PER CENT INTEREST, IN GOLD, TO SEND IN THEIR ORDERS BEFORE THAT TIME.

These Bonds are the CHEAPEST GOVERNMENT SECURITY NOW IN THE MARKET, and pay the LARGEST INTEREST on their cost, and Congress has provided that they shall be paid in GOLD, when due.

They are destined to become the BEST KNOWN, MOST POPULAR and MOST AVAILABLE, of all the Bonds of the Government.

The operation of the National Tax Law, which it is now certain will produce double the income originally anticipated, will make the issues of the United States Government the safest and most desirable investment in the world. They are in reality a First Mortgage on everything in the country, as no Railroad or Corporation of any kind, can pay a dividend, or the interest on its own issues, until it has contributed out of its gross income, through the operation of the Tax Law, to the support of the National Credit.

The present bonded debt of the United States is less than THREE HUNDRED MILLIONS, including the seven and three-tenths Treasury Notes; but the Government owes enough more in the shape of Legal Tenders, deposits in the Sub-Treasuries, Certificates of Indebtedness, &c., to increase the debt to about eight or nine hundred millions. Secretary Chase has calculated that the debt may reach one thousand seven hundred millions if the Rebellion lasts eighteen months longer. It is, however, believed that it will not last six months longer—but even if it does, the National Debt will be small compared with that of Great Britain or France, while our resources are vastly greater.

There is no doubt that the revenue will not only be ample to pay the ordinary expenses of the Government, and all in interest on the debt, but leave at least one hundred millions annually toward paying off the debt, and that the Government will be able to get out of debt again, as it has twice before, in a few years after the close of the war.

The duties on imports of all articles from abroad must be paid in GOLD. It is now being paid into the Treasury at the rate of Two Hundred Thousand Dollars each day, which is twice as much as is needed to pay the interest in Gold on all the Bonds of the Government.

The Supreme Court of the United States have just decided that the States have no power to tax the Securities of the Government. This is conclusive upon this point, and will greatly increase the value of these securities.

As the right to convert Legal Tender Notes into FIVE TWENTY Bonds expires on the 1st of July, those having funds in Savings Banks, the interest upon which would be forfeited if withdrawn before that day, can secure bonds, to be delivered during the first 20 days of July, by a deposit of 10 per cent with the subscribers.

We also deal in all classes of United States Securities, and buy and sell Stocks and Bonds on Commission.

We pay special attention to orders from the Country. **FISK & HATCH,**
No. 38 Wall-st., New-York.

Colcus Verschaffeltii.

The undersigned, having a large stock of the above new, rare, and beautiful bedding plant, offers it at the reduced price of 50 cts. each. The usual liberal discount to the trade. Plants can be obtained at McIlvain & Young's seed store, No. 9 John-st., Harvey B. Lane, 151 Nassau-st., or at C. B. Miller's, 634 Broadway.

ONION CULTURE—Fourth (new) Edition.

This work comprises in 32 pages all the particulars for successful Onion Culture, from Selection of Seed to Marketing the Crop—being the practical directions given by seventeen experienced Onion Growers, residing in different parts of the country. Price 20 cents (or 7 stamps), sent post-paid. Address Publisher of *Agriculturist*.

TOBACCO.**Just How to Grow it.**

Every particular, from the selection of the Seed, and preparation of the ground, to the Gathering, Curing, and Marketing the Crop, is given in a work issued by the Publisher of the *American Agriculturist*, and sent post-paid for 25 cents. This work consists of a selection of the best fourteen out of eighty-five Essays, prepared by eighty-five different cultivators, residing in various parts of the Northern and Middle States. In each of the Essays contained in this work, the writer tells, in a plain, practical, straight-forward manner, just what to do, and how to do it. Any item omitted by one is given by another, so that the information is full and complete. Several engravings illustrating the method of drying, packing, etc. The work is worth its weight in silver to every one growing even a small plot of tobacco.

BOOKS FOR FARMERS AND OTHERS.

[Any of the following books can be obtained at the office of the *Agriculturist* at the prices named, or they will be forwarded by mail, *post paid*, on receipt of the price. Other books not named in the list will be procured and sent to subscribers when desired, if the price be forwarded. All of these books may be procured by any one making up a library. Those we esteem specially valuable, are marked with a *.]

N. B.—For books going over 1,500 miles, 18 cents extra on each dollar's worth must be sent to us to pre-pay the extra postage, and in the same ratio for fractional parts of a dollar.
